TEST & MEASUREMENT GROUP
OF
SYSTRON DONNER
WARRANTY POLICY

I – Warranty

The Test & Measurement Group of Systron Donner warrants that at the time of shipment the products manufactured by Systron Donner's T&M Group and sold hereunder will be free from defects in material and workmanship and will conform to the specifications furnished by or approved in writing by Systron Donner's T&M Group.

II – Warranty

A – The warranty period for products published in our latest product catalog will be one year from the date of shipment. This warranty is extended only to the original buyer.

B – The warranty period for products published in prior catalog, will be 90 days from the date of shipment.

C – The warranty period for modified standard products, custom products, or new spare part assemblies will be 90 days from the date of shipment.

D – The warranty period for systems or assemblies of miscellaneous components and products will be limited to the warranty for the stand alone component or instrument. The system itself is not guaranteed unless a specific installation and service agreement has been negotiated between Systron Donner and the customer. In this latter case, the warranty period will be 30 days after the installation of the system while the various portions of the system will be limited to the normal component or instrument stand alone warranty, and for non Systron Donner material within the system that is furnished by Systron Donner the warranty will be limited to the suppliers normal warranty.

III – Warranty Adjustments

A – If any defect within this warranty appears, Purchaser shall notify Seller immediately.

B – Systron Donner's T&M Group agrees to repair or furnish a replacement for, but not install, any product which, within the standard warranty shall, upon test and examination by Systron Donner's T&M Group, prove defective within the above warranty period.

C – No product will be accepted for return or replacement without the written authorization of Systron Donner's T&M Group. Upon such authorization and in accordance with instructions by Systron Donner's T&M Group, the product will be returned to the original manufacturing location, shipping charges prepaid by Purchaser.

IV – Exclusions from Warranty

A – The foregoing warranty is in lieu of and excludes all other expressed or implied warranties of merchantability or fitness or otherwise.

B – Systron Donner's T&M Group will not be liable for any special or consequential damages or for loss, damages or expense directly or indirectly arising from the use of the products, or any inability to use them either separately or in combination with any other equipment or material, or from any other cause.

C – The warranty does not extend to any product manufactured by Systron Donner's T&M Group which has been subjected to misuse, neglect, accident, improper installation or to use in violation of instructions furnished by Systron Donner's T&M Group.

D – The warranty does not extend to or apply to any unit which has been repaired or altered at any place other than at a Systron Donner T&M Group factory, by persons not expressly approved by Systron Donner's T&M Group, not to any unit, the serial number of which has been removed or defaced or changed.

E – This warranty applies to new equipment only and will cover repaired or replacement items only to the extent of the balance remaining of the items original warranty period noted above in Paragraph II.

F – All freight charges will be paid for by the Purchaser.

Divisions in the Test & Measurement Group include:

Instrument Division – Concord, CA
WM Division – Sacramento, CA
ACD Division – Sunnyvale, CA
SD GmbH – Munich, West Germany

Thank You.

e appreciate your confidence in our products. Systron-Donner wishes ensure your on-going satisfaction with this instrument by maintaining at its specified performance throughout its warranty period. If assistance required, please feel free to contact one of our Factory, Regional or ocal Service Centers listed on the reverse side of this card.

service, calibration or parts are required beyond the warranty period, ease contact the Service Center nearest you. They will ensure your ntinuing satisfaction with our equipment.

o insure complete warranty coverage of this instrument and to help us rve you better, please complete the warranty registration card and turn it immediately.

Sincerely,

A J "Butch" Griffin

CHAPTER 1
GENERAL INFORMATION

1.1 INTRODUCTION

The Model 7110A Digital Multimeter (DMM) is an integrating, dual slope, highly accurate, system compatible, digital multimeter. A full five digit readout plus an overrange digit and five measurement ranges of dc/dc ratio are provided in the basic unit. The Model 7110A combines fast measurement speed with excellent normal mode noise rejection at line related frequencies.

The dual-slope integration technique is used in the Model 7110A. At the time of a typical measurement, the unknown input voltage causes a current to flow in an integrating capacitor for a length of time determined by an internal clock. During this time period the capacitor will charge to a voltage proportional to the input voltage. After this charging period, an internal reference current is used to discharge the capacitor; and the time is measured with the internal clock oscillator and the digital counting chain. The count, proportional to time, is a measure of the input voltage.

1.2 SPECIFICATIONS

DC Volts (VDC FUNCTION)	Ranges	±100.000 mV, ±1000.00 mV, ±10.0000 V, ±100.000 V, and ±1000.00 V full scale plus 30% overrange on all ranges except 10% on 1000 volt range.
	Resolution	0.001% of range (1 µV on 100 mV range).
	Input Resistance	10,000 MΩ on .1, 1, 10 V ranges; 10 MΩ on 100, 1000 V ranges.
	Accuracy (+23 °C ±1 °C, up to 130% of range)*	1, 10, 100, and 1000 Volt Range: ±0.005% rdg. ±0.001% full scale for 24 hrs.; ±0.008% rdg. ±0.003% full scale for 3 months. 0.1 Volt Range: ±0.005% rdg. ±0.005% full scale for 24 hrs.; ±0.01% rdg. ±0.01% full scale for 3 months.
	Temperature Stability (0 to 50 °C, up to 130% of range)	1, 10, 100, and 1000 Volt Range: ±0.001% rdg. ±0.0003% full scale/°C. 0.1 Volt Range: ±0.001% rdg. ±0.002% full scale/°C.

DC Volts (VDC FUNCTION) (Cont'd)	Full-Scale Settling Time (to ±0.01%)	FILTER out: 20 ms on 1, 10, 100, and 1000 volt ranges; 150 ms on 0.1 volt range FILTER in: 800 ms on all ranges.
	Normal Mode Noise Rejection	FILTER out: 60 dB at 60 Hz (60 dB at 50 Hz with Opt. 01). FILTER in: 80 dB at 60 Hz (80 dB at 50 Hz with Opt. 01).
	Common Mode Rejection (1 kΩ unbalance)	140 dB at dc; 120 dB up to 60 Hz.
	Maximum Input	±1000 volts dc on any range except ±1100 volts on 1000 V range.
DC Ratio (RATIO FUNCTION)	Ranges	±.010000:1, ±.100000:1, ±1.00000:1, ±10.0000:1, and ±100.000:1 full scale plus 30% overrange on all ranges.
	Unknown Input (Ex)	±1 μV to ±1100 V maximum.
	Reference Input (Eref)	+2 volts to +11 volts; maximum input +13 volts without damage.
	Input Resistance	Ex: 10,000 MΩ on .01, .1, and 1:1 ranges; 10 MΩ on 10 and 100:1 ranges. Eref: 1 MΩ between each input terminal and signal low on all ranges.
	Configuration	4-wire system with isolated commons. Max. differential between Ex and Eref commons is ±2 volts. Ex input on front panel (rear panel with Opt. 08). Eref input on rear panel only.
	Accuracy (+23 °C ±1 °C, up to 130% of range)*	.1:1, 1:1, 10:1, and 100:1 Ranges: 0.01% rdg. ±0.002% full scale + (10/Eref) X 0.003% for 3 months. .01 Range: 0.01% rdg. 0.005% full scale + (10/Eref) X 0.003% for 3 months.

DC Ratio (RATIO FUNCTION) (Cont'd)	Temperature Stability (0 to +50 °C, up to 130% of range)	.1:1, 1:1, 10:1, and 100:1 Ranges: (±0.001% rdg. ±0.0003% full scale) 10/Eref per °C. .01:1 Range: (±0.001% rdg. ±0.002% full scale) 10/Eref per °C.
	Full-Scale Settling Time	Same as DC Volts.
	Normal and Common Noise Rejection	Same as DC Volts.
	Maximum Input (Ex)	±1000 volts on any range except ±1100 volts on 100.000:1 range.

*Specifications shown are maintained with no adjustment. Substantially improved accuracy for 0.1 (DC volts) or 0.01:1 (DC/DC ratio) range may be obtained with periodic re-zeroing of front panel mV ZERO adjustment which also is designed to offset effects of low level thermals in measuring leads or input cables.

AC Volts (VAC FUNCTION) Option 02	Ranges	1.00000 V, 10.0000 V, 100.000 V, and 1000.00 V full scale plus 30% overranging on all ranges except 1000 V (750 volts max.)
	Input Impedance	1 MΩ shunted by 70 pF (120 pF with Opt. 08).
	Accuracy (+23 °C ±5 °C; 1% of full scale and above)	±0.1% rdg. ±0.02% full scale for 3 months at all frequencies from 50 Hz to 100 kHz (except 50 Hz to 20 kHz on 1000 V range).
	Full-Scale Settling Time (to ±0.1%)	500 ms, maximum.
	Conversion Method	Average responding scale factored to rms.
	Maximum Input	750 V rms at all frequencies up to 100 kHz.
	Resolution	0.001% of range (10 µV on 1 V range).

Resistance (KΩ FUNCTION) Option 03

Range	Current thru Rx	Resolution
.100000 kΩ	1 mA	1 mΩ
1.00000 kΩ	1 mA	10 mΩ
10.0000 kΩ	1 mA	100 mΩ
100.000 kΩ	100 µA	1 Ω
1.00000 MΩ	10 µA	10 Ω
10.0000 MΩ	1 µA	100 Ω

Overrange	30% on all ranges.
Measurement Technique	4 wire Ω measuring configuration.
Accuracy (+23 5°C)	1, 10, 100, 1000, and 10,000 kΩ Ranges: ±0.01% rdg. ±0.005% full scale for 3 months. .1 kΩ Range: ±0.01% rdg. ±0.01% full scale for 3 months.
Full-Scale Settling Time (to 0.01%)	500 ms maximum on .1 kΩ to 1000 kΩ ranges; 3 second maximum on 10,000 kΩ range.
Maximum Input	Up to 1000 volts may be applied across current source or resistance input terminals.
Temperature Stability	1 kΩ to 10,000 kΩ Ranges: ±0.0015% rdg. ±0.0003% full scale per °C.
	.1 kΩ Range: ±0.0015% rdg. ±0.002% full scale per °C.

Digital Outputs Option 05

This option includes parallel 1-2-4-8 outputs of all measurement data, function, and decimal point with output flag lines provided for Data Ready (i.e. Print Command) and Busy (i.e. Inhibit) conditions. All outputs are buffered, short-circuit proof and fully isolated. Logic levels are DTL/TTL compatible, positive true:
"1" State (true) = +4(±0.5) volts, 6 kΩ source.
"0" State (false) = 0.5 (±0.5) volts, 12 mA sink.

Print Command output transition is from logic "0" to "1" State. Inhibit (Busy) signal is activated by a logic ground. This option must be ordered for remote control of sample rate (single reading, stop, memory update, stop new measurement cycles-ground logic activated). Output connector is Amphenol 50 pin type 57-40500; mate is type 57-30500.

Remote Programming Option 06	Allows remote control of all RANGE, FUNCTION, and FILTER selections in single-line format. All external control is DTL/TTL compatible, ground true logic. "1" State (line called) = logic ground or +0.5 volts, maximum. "0" State (line not called) = open ckt. or +2.2 volts, minimum. Output connector Amphenol 24 pin type 57-40240; mate is type 57-30240.	
Rear Panel Inputs (Option 08)	Ratio, Signal input and ohms current source connectors are triaxial BNC; King type KC79-85.	
True RMS AC Volts (VAC FUNCTION) Option 10	Ranges	1.00000 V, 10.0000 V, 100.000 V, and 1000.00 V full scale plus 30% overranging on all ranges except 1000 V (750 volts max.)
	Resolution	0.001% of range (10 μV on 1 V range).
	Crest Factor	7 at full scale, increasing down scale per: $7\sqrt{V \text{ range}/V \text{ input}}$
	Conversion Method	Logarithmic operator performing continuous squaring, integration and square root functions. The dc output is proportional to the true rms value of the waveform at the accuracy specified below.
	Input Impedance	1 MΩ shunted by <70 pF (120 pF with Option 08).
	Input Configuration	dc coupled; computes dc + ac rms value of input. External capacitor may be added at input terminals to block the dc and measure the ac component only.
	Superimposed dc	1000 volts max. (peak ac + dc must not exceed 1000 volts).
	Accuracy (+23 °C ±5 °C, 90 days, 1% of full scale and above)	dc + 50 Hz to 10 kHz: ±0.1% rdg. ±0.05% full scale. dc + 10 kHz to 20 kHz: ±0.3% rdg. ±0.2% full scale. dc + 20 kHz to 100 kHz: ±1.0% rdg. ±0.5% full scale. dc + 100 kHz to 300 kHz: ±3.0% rdg. ±0.5% full scale.

True RMS AC Volts (VAC FUNCTION) Option 10 (Cont'd)	Temperature Stability (0 to +18 °C; +28 to +50 °C)	50 Hz to 10 kHz: ±0.015% rdg. ±0.004% full scale/°C. 10 kHz to 300 kHz: ±0.02% rdg. ±0.02% full scale/°C. *NOTE: Input volts x Hz product should not exceed 2 x 10^7.*
	Maximum Input	750 volts rms on any range.
	Full-Scale Settling Time	1 s.
	External dc Blocking Capacitor	0.1 µF, 1200 V mylar in series with HI input.
General	Display	5 full digits plus overrange digit of gas discharge tubes. Automatic decimal point positioning for all ranges and functions. Lighted annunciator for all functions and ratio ranges. Warning lamp lighted for imcompatible range/function setting or options not installed. Plus/minus and off-scale indicator provided.
	Range Selection	Manual and automatic. Remote range selection with Option 06.
	Input Configuration	Fully floating and guarded in all functions.
	Maximum Common Mode Voltage	500 volts dc or peak ac.
	Offset Current	25 pA maximum at +23 (±1) °C. Doubles for every ±10 °C change in temperature.
	Output (Kickback) Noise	Typically less than 1 mV rms, dc to 1.5 kHz across 1 MΩ impedance.
	Sample Rate	Adjustable from approximately 10 samples per second to 1 sample per 10 seconds from front panel control. FAST position provides fixed sample rate of approximately 30 samples per second. HOLD position allows single sample.

General (Cont'd)

Autoranging Time (Does not include amplifier settling time, measurement time,or transfer time to storage):

RANGE From	To	Ranging Time	RANGE From	To	Ranging Time
0.1	1	80 ms	10,000	1000	80 ms*
1	10	80 ms	1000	100	120 ms
10	100	120 ms	100	10	80 ms
100	1000	80 ms	10	1	80 ms
1000	10,000	80 ms*	1	0.1	80 ms

* (Resistance Only)

NOTE: (1) Settling time starts concurrent with arrival of 7110A at correct range.

(2) Two readings are taken on arrival at correct range prior to display update or print command output.

(3) Upranges at 130,000 counts; Downranges at 10,999 counts.

Settling Time	See specifications under each function.
Integration (Aperture) Time	Time 7110A looks at input; fixed 16.67 ms (20 ms with Option 01).
Digitizing Time	0 to 16.67 ms (0 to 20 ms with Option 01) corresponding to 0 to 100% of full scale in a linear relationship. Occurs after completion of integration interval.
Transfer-To-Storage Time	Nominal 10 µs delay prior to display update and print command issuance after completion of digitizing interval.
Calibration	All calibration controls and test points are accessible by removing top cover. No special tools are required for calibration.
Temperature Range	0 to +35 °C at up to 80% relative humidity; 0 to +50 °C at up to 70% relative humidity, noncondensing.

General (Cont'd)	Warm-up	30 minutes to full accuracy.
	Dimensions	8.9H x 43.2W x 44.5D cm (3 1/2 x 17 x 17 1/2 in). Integral tilt stand for bench use. Chassis drilled for Johnathan 120 QD Series slides.
	Power	100/200 or 115/230 switch selectable (specify on order) VAC (±10%), 58-62 Hz, 75 watts. (Option 01 for 50 Hz use).
	Weight	9.5 kg. (21 lb.) net; 16 kg. (35 lb.) shipping.

CHAPTER 2
INSTALLATION

2.1 INTRODUCTION

This chapter outlines the procedures for initial inspection and installation of the Model 7110A Digital Multimeter (DMM). Instructions for reshipment are included should the Model 7110A require return to the Systron-Donner Corporation.

2.2 RECEIVING INSPECTION

Prior to accepting the meter from the shipper, inspect the condition of the shipping container for any indication of freight damage. Any sign of such damage must be noted by both the shipper and receiver and should be reported to the insurance investigator.

Immediately following the removal of the meter from the shipping carton, inspect for possible physical damage incurred during shipment. Check surface for scratches or dents and note the condition of knobs and connectors. Should any damage be noted, notify your nearest Systron-Donner representative---DO NOT USE THE METER UNTIL INSTRUCTED TO DO SO BY THE REPRESENTATIVE.

2.3 RESHIPMENT

If possible, use the original packing materials. Your Systron-Donner field office can provide materials similar to those used for the original factory packaging.

GENERAL PACKING INSTRUCTIONS

1) Wrap the instrument in heavy paper or plastic prior to placing into the shipping container.
2) Use a strong carton or wooden box to house the instrument.
3) Use ample packing material on all sides and protect the front panel with cardboard strips.
4) Seal the package with strong tape or metal bands and mark "DELICATE INSTRUMENT" on all sides.
5) All correspondence should refer to full instrument nomenclature (model and serial number).

2.4 POWER REQUIREMENTS

The Model 7110A Multimeter is equipped with a three-conductor power cord that automatically grounds the meter (chassis ground) when a matching power receptacle is employed. An adapter which provides a chassis ground should be used whenever the power cord is mated to a two-terminal outlet.

The Model 7110A operates from either 115 or 230 V rms at 50 or 60 Hz and draws approximately 30 watts of power. A LINE switch on the rear panel is used to select the desired voltage.

NOTE

The Model 7110A DMM is shipped with a 3/4 A 3AG fuse (115V operation). Should 230V operation be employed, the standard 3/4 A 3AG fuse should be replaced with a 3/8 A 3AG fuse to adequately protect the meter.

2.5 LOCATION SITE

The Model 7110A DMM employs forced-air cooling. The air outlet on the rear panel must remain unobstructed while the meter is energized.

2.6 INITIAL TURN-ON

This procedure verifies that no major damage has occurred to the instrument during transit, and that the instrument is operative.

NOTE

Prior to performing the initial turn-on procedure, become familiar with the instrument's controls as described in Section 3.2 Controls, Connectors, and Indicators.

1) Check the position (115V-230V) of the LINE switch and connec the ac power cord to the appropriate power source.
2) Depress the POWER switch to the ON position. The display should illuminate.
3) Push the VDC FUNCTION switch and the 10 RANGE switch. Apply a short across the SIGNAL INPUT HI and LO terminals. Display should indicate ±00.0000/±2 digits and the VDC annunciator should illuminate. Remove the short.
4) Push-on the TEST FUNCTION switch. The display should read, +10.0000 ±3 digits.

After the instrument has successfully completed the initial turn-on procedure, refer to the Acceptance Test Procedure, Section 3.7 .

CHAPTER 3
OPERATION

3.1 INTRODUCTION

This chapter describes the Model 7110A Digital Multimeter (DMM) operating procedures. Included is a table of the instrument controls, connectors, and indicators followed by a brief section on overload protection and guard circuit usage. Delineation of the manual, remote, and system operation of the DMM precedes the concluding acceptance test procedure.

3.2 CONTROLS, CONNECTORS, AND INDICATORS

The various controls, connectors, and indicators of the Model 7110A DMM are described in Table 3.1 Front Panel and Table 3.2 Rear Panel. Figures 3.1 and 3.2 provide indexed locations of each item in the tables.

TABLE 3.1 FRONT PANEL, MODEL 7110A
(See Figure 3.1)

Index	Name		Function
1	POWER (pushbutton)		The "in" position turns the main power on.
2	READOUT (indicator)	O.S., RATIO,* mVDC, VDC 10^{-3}, VAC MΩ, KΩ	In the readout display left hand annunciator, O.S. indicates that the last reading is above 1.3 times the full scale of the range and the accuracy should be questioned. RATIO indicates that an external reference is being used and the number displayed is the ratio of the unknown voltage and this external reference. * indicates that an improper FUNCTION and RANGE combination has been selected. The right hand annunciator includes mVDC, VDC, VAC, MΩ, and KΩ function indicators. 10^{-3} is used with the RATIO FUNCTION in the .1 RANGE to multiply the readout by .001.

TABLE 3.1 FRONT PANEL, MODEL 7110A (Cont'd)

Index	Name		Function
3	FUNCTION (pushbuttons)	FILTER, VDC VAC, KΩ, RATIO, TEST REMOTE	FILTER is push-on push-off type. When in the depressed position the input attenuator filter is connected between the input terminals and the input amplifier, providing about 80 dB of normal mode attenuation at 60 Hz. VDC, VAC, KΩ, RATIO, TEST, and REMOTE are all interlocked functions.
4	mV ZERO (control)		This screwdriver adjust potentiometer controls zeroing of the DVM with the input shorted in the VDC FUNCTION and .1 RANGE.
5	SAMPLE/RATE (control)	HOLD	This control varies the sample rate from 30 per second in the counterclockwise detent position and from 10 samples per second to 1 sample per 10 seconds. HOLD detent position allows a single sample from front panel SINGLE pushbutton.
6	SAMPLE/SINGLE (pushbutton)		Allows a single sample when pushed. RATE in HOLD.
7	INPUT (switch)	FRONT REAR	Selects either front or rear inputs.
8	RANGE (pushbuttons)	.1, 1, 10, 100, 1,000, 10,000, AUTO	These full scale ranges are applied to the FUNCTION selected.
9	CASE, metal (connector)		Universal binding post with metal cap provides a chassis ground terminal.
10	GUARD, grey plastic (connector)		Universal binding post for guard connection.
11	Ω CURRENT SOURCE/LO, black plastic (connector)		Universal binding post for current source negative.

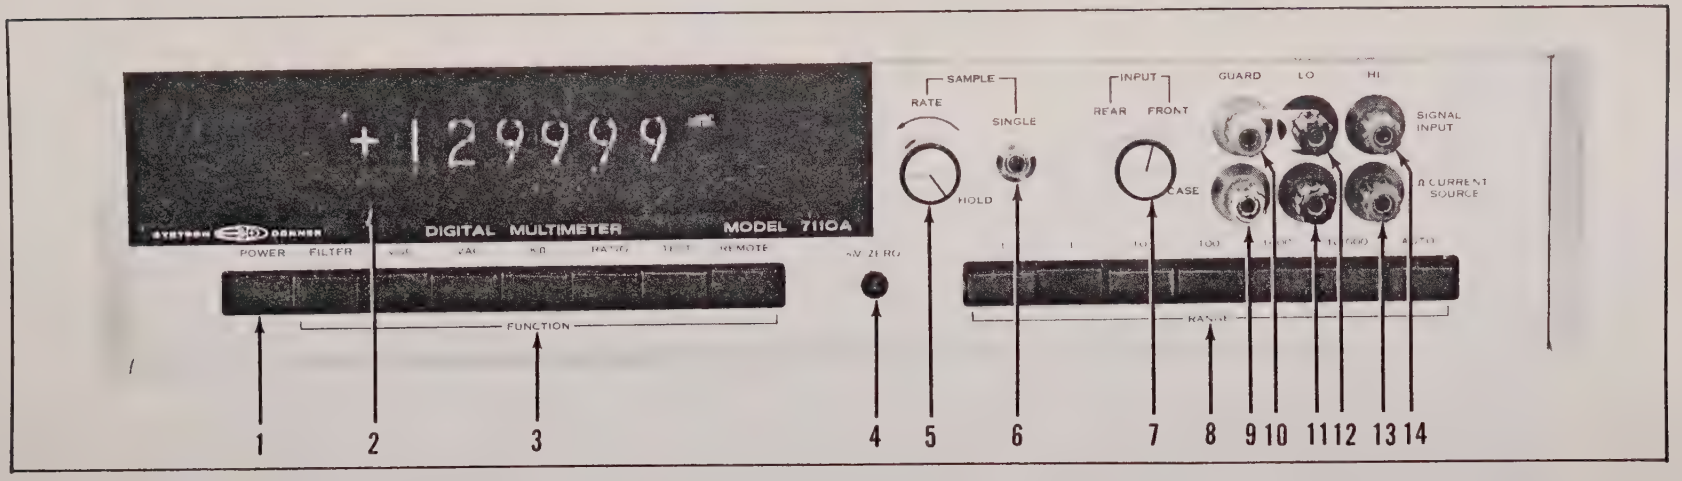

FIGURE 3.1 FRONT PANEL, MODEL 7110A

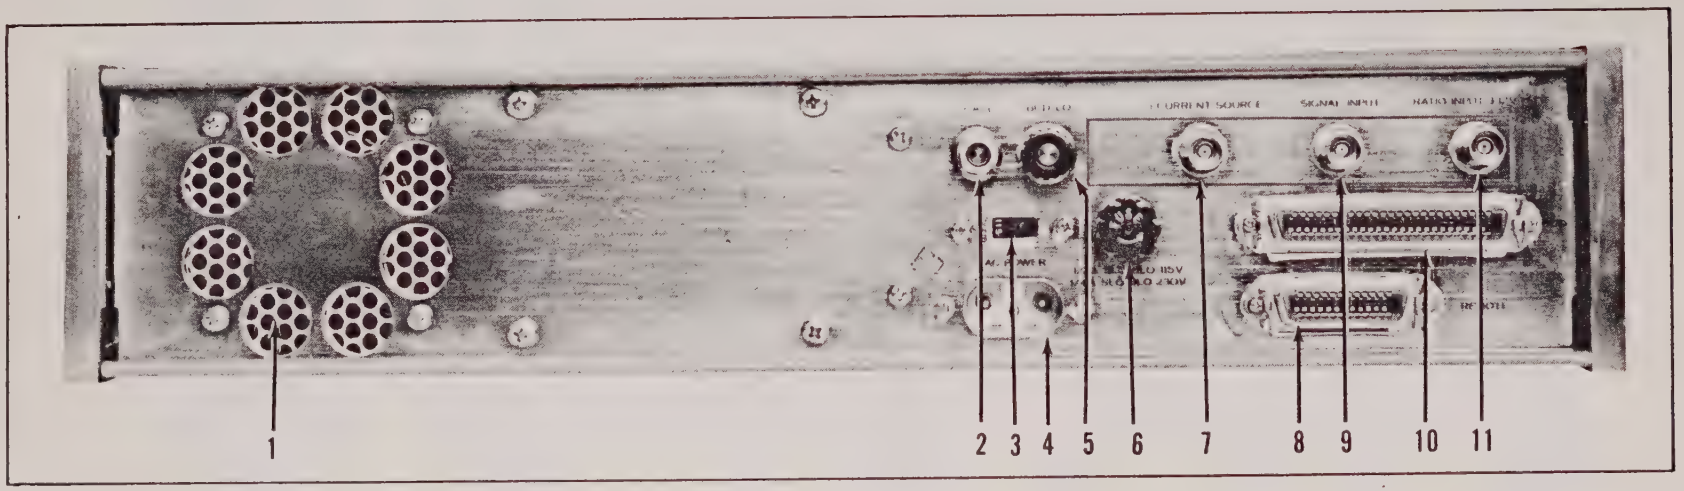

FIGURE 3.2 REAR PANEL, MODEL 7110A

TABLE 3.1 FRONT PANEL, MODEL 7110A (Cont'd)

Index	Name		Function
12	SIGNAL INPUT/ LO, black plastic (connector)		Universal binding post for negative side of input signal.
13	Ω CURRENT SOURCE/HI, red plastic (connector)		Universal binding post for current source positive.
14	SIGNAL INPUT/ HI, red plastic (connector)		Universal binding post for positive side of signal source.

TABLE 3.2 REAR PANEL, MODEL 7110A

Index	Name		Function
1	FAN EXHAUST		Cooling air is exhausted through this opening. Do not obstruct this air outlet.
2	CASE, metal (connector)		Universal binding post for rear panel chassis ground.
3	AC POWER (switch)	115/230	This switch selects either 115 V or 230 V ac power source.
4	AC POWER (connector)		This power cord receptacle allows connection of either 115 V or 230 V ac power.
5	BCD LO (connector)		Universal binding post for rear panel BCD output common.
6	FUSE (holder)	3/4 A SLO BLO 115 V, 3/8 A SLO BLO 230 V	This holder contains the main power fuse. Be sure to change fuse to match the AC voltage selected.
7	Ω CURRENT SOURCE OPTION 08 (connector)		When the input is switched to the rear panel this triaxial BNC type connector acts as the HI (center conductor) and LO (middle conductor) Ω CURRENT SOURCE terminals. The outer shell

TABLE 3.2 REAR PANEL, MODEL 7110A (Cont'd)

Index	Name	Function
7 (Cont'd)		is a current shield separate from the GUARD circuit.
8	REMOTE OPTION 06,301,302 (connector)	This 24-pin connector provides remote control of the Model 7110A.
9	SIGNAL INPUT OPTION 08 (connector)	When the input is switched to the rear panel this triaxial BNC type connector acts as the HI (center conductor), LO (middle conductor), and GUARD (outer conductor) terminals.
10	BCD OPTION 05 (connector)	This 50-pin connector provides parallel BCD outputs of all measurement data plus flag lines for Data Ready and Busy conditions.
11	RATIO INPUT +12 V MAX (connector)	This triaxial BNC type connector provides +12 V Max inputs for ratio measurements. Positive is on the center terminal, Negative on the middle terminal, and Guard on the outer shell.

3.3 OVERLOAD PROTECTION

The Model 7110A Digital Multimeter can withstand 1000 V dc in all ranges on the HI and LO SIGNAL INPUT connectors. The LO side may be floated above chassis ground not to exceed 500 V dc. The rear panel RATIO INPUT +12 V MAX connector may only accept a maximum voltage of +12 V dc.

3.4 GUARD USAGE

For increased rejection of ac and dc (Common Mode Rejection)* voltages during measurements, a GUARD shield has been provided on the front and rear panels of the Model 7110A DMM. In measurements where common mode voltages are not expected to be a problem, the GUARD binding post may be connected to the SIGNAL INPUT LO terminal using the shorting strap provided.

*CMR = Common Mode Rejection

CAUTION

Do not leave the GUARD floating since the 500 V dc limitation between the GUARD and LO terminals may be exceeded.

Where common-mode voltages will present significant readout errors such as voltages found in the source circuitry between SIGNAL SOURCE LO and power line ground, measurements should be made with the GUARD connected at the source. The GUARD should be connected to a dc potential above ground equal to the LO input terminal potential above ground in such a way that the GUARD current does not flow through any source circuit impedance affecting the measured voltage.

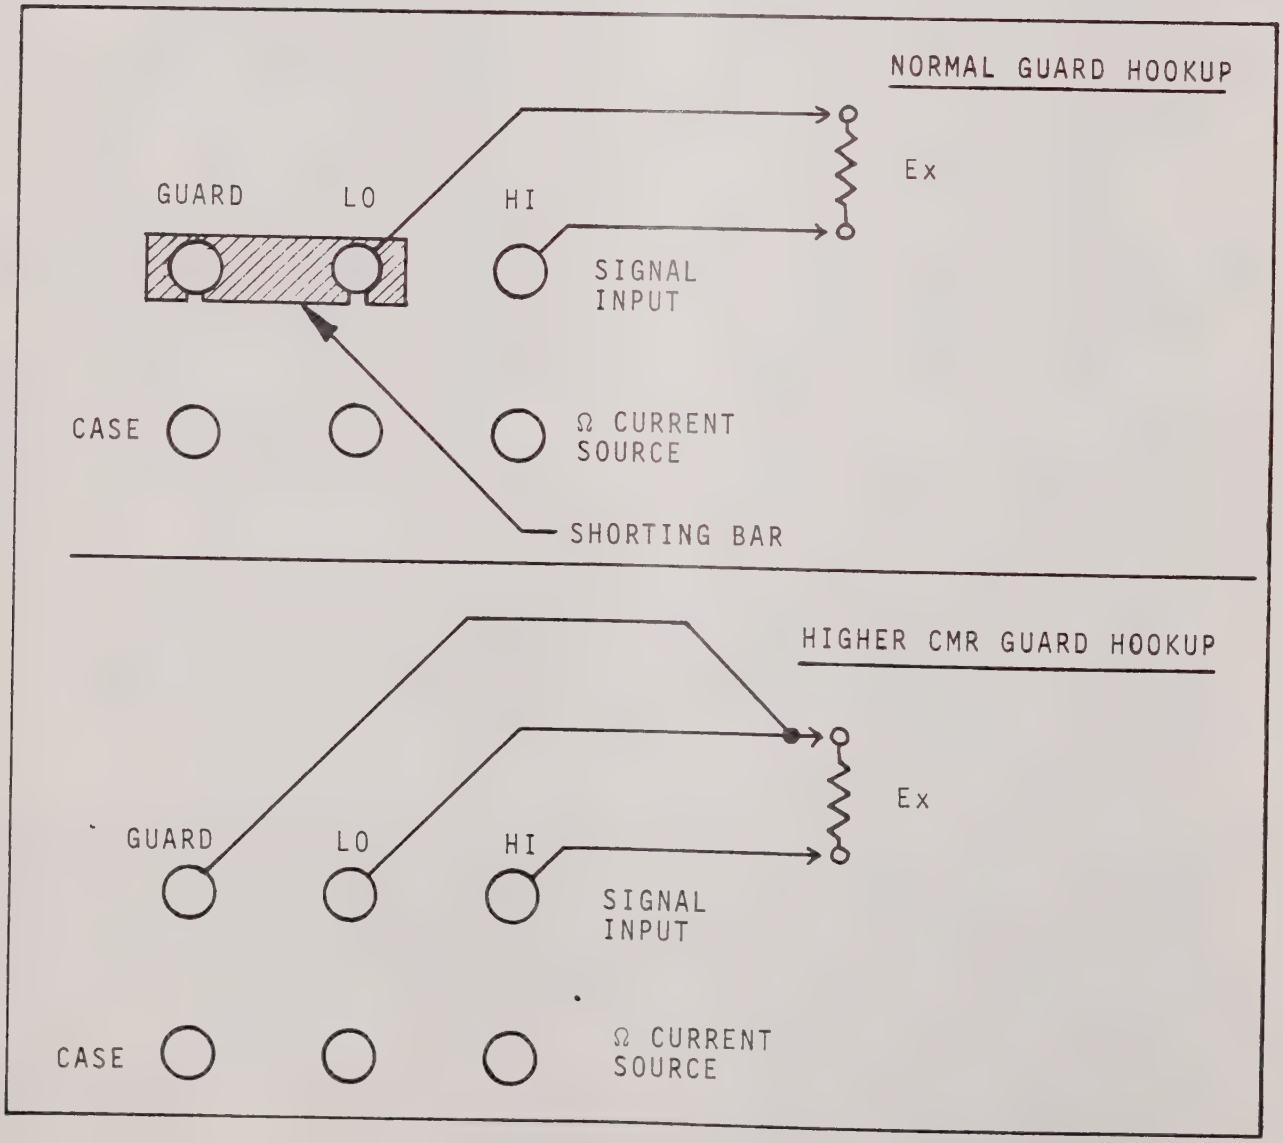

FIGURE 3.3 GUARD USAGE.

* Improper FUNCTION/RANGE pushbutton combination.

⊡ □ If option is installed.

* If option is not installed.

3.5 MANUAL OPERATION

Manual operation of the Model 7110A includes local control of all DMM functions and ranges. Common controls for all manual modes of operation are:

SAMPLE RATE controls	Set the knob to the desired sampling rate either fast, variable, or HOLD with pushbutton single sample.
FRONT-REAR INPUT switch	Select either front or rear input (with Option 08 only).
FILTER pushbutton	The "in" position provides 80 dB of common mode noise rejection at 60 Hz.
REMOTE pushbutton	This allows operating the unit from the rear panel REMOTE inputs when Option 06 is installed.
TEST pushbutton	This function displays 100,000 counts and is used for calibrating the instrument.

For all operations, the DMM should be on for at least 30 minutes to reach specified accuracy.

3.5.1 VDC Operation

Push on the POWER switch and allow the DMM to warm up. Select the VDC FUNCTION and an appropriate RANGE pushbutton. Note that AUTO will allow the unit to select the appropriate range automatically. If manually selecting the range, choose one with the desired resolution without an off scale (O.S.) indication. With the INPUT switch, select FRONT for front panel signal input or REAR for rear panel signal input. Set the SAMPLE RATE in the counterclockwise detent position and push on the filter for added noise rejection. Couple the dc voltage to the SIGNAL INPUT HI and LO terminals. Leave the GUARD shorted to the LO terminal unless added shielding is needed or the dc source has a GUARD terminal.

3.5.2 VAC Operation

Push the VAC and appropriate RANGE pushbuttons and push off the FILTER button. Apply the ac signal to the HI and LO SIGNAL INPUT terminals. The sample RATE control may be varied for the desired sampling rate.

3.5.3 KΩ Operation

Push the KΩ pushbutton and select a range. Connect an unknown resistor across the SIGNAL INPUT HI and LO terminals and then connect the Ω CURRENT SOURCE HI and LOW terminals across the resistor. The reading will be a measure of the voltage between the two points developed by the current flow in the resistor.

If using the rear inputs for the Ω CURRENT SOURCE, a double-shielded dual coax lead should be used with the rear panel triaxial BNC connector (see Figure 3.4). The shield for each HI and LO lead should be tied together and to the outer shell of the triaxial BNC which is the Ω CURRENT SOURCE common. The second outer shield should be connected to the GUARD terminal, available on the outer shell of the SIGNAL INPUT triaxial connector. A special cable material, specification #37534-6-1, is available for systems connections.

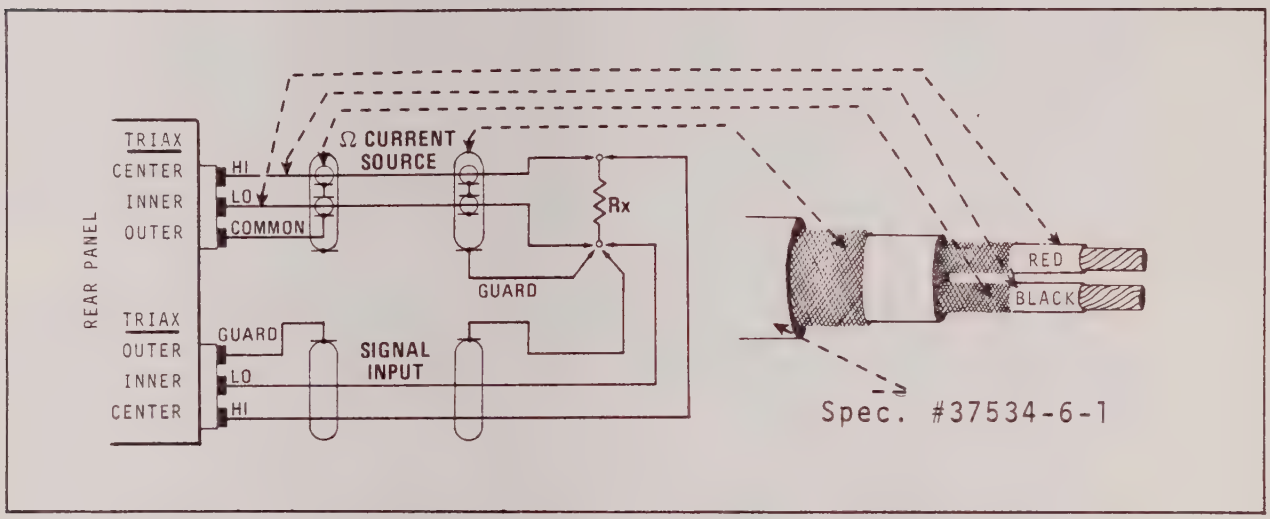

FIGURE 3.4 REAR PANEL Ω CURRENT SOURCE TRIAX CABLE CONNECTION.

Where resistances greater than 10 MΩ are to be measured with a computer controlled system, one can make an accurate measurement by first measuring a precision resistor of 10 MΩ or less (R1) and then making a second measurement with the unknown high-value resistor (Rx) in shunt with R1. The system's computer can then calculate the product of the two measurements divided by their difference. For example, if R1 is 10 MΩ, an unknown shunt resistance, Rx, of $10^{12}\Omega$ would cause a one digit difference between the two readings. This procedure may therefore be used to measure resistance values between 10^{6} and 10^{12} ohms and may be easily programmed into systems using a computer:

Equation 1

$$Rx = \frac{R1 \cdot R2}{R1 - R2}$$

where: R2 = resistance of parallel combination of R1 and Rx

3.5.4 Ratio Operation

Select the RATIO and an appropriate range pushbutton. Select FRONT or REAR INPUT and connect +2 to +11 volts between the inner shield and the center conductor of the RATIO INPUT triaxial connector with the positive of the external reference on the center conductor. The positive and negative of the external reference should not be more

positive than +12 volts or more negative than -12 volts with respect to the LO SIGNAL INPUT connection.

3.6 REMOTE OPERATION

Remote operation includes the Remote Control Option 06 and the BCD Data Out Option 05.

3.6.1 Remote Control, Option 06

With Option 06 installed, the Model 7110A may be operated remotely using single line format. Control is provided over all RANGE and FUNCTION pushbuttons with DTL/TTL compatible ground true logic - "1" state (line called) = logic ground or +0.5 V dc maximum, "0" state (line not called) = open circuit or +2.2 V dc minimum. The connector type is a 24 contact Amphenol 57-40240 and mates with Amphenol 57-30240.

Press on the POWER and REMOTE pushbuttons, set the sample control to the desired rate, and remotely select the RANGE and FUNCTION of J208. The proper PIN and RANGE association is listed in Table 3.4 REMOTE PIN ASSIGNMENTS.

TABLE 3.4 REMOTE PIN ASSIGNMENTS, OPTION 06
(J208 REMOTE connector is Amphenol 57-40240)

PIN	SELECTED FUNCTION/RANGE[1]
1	REMOTE COMMON[2]
3	VDC
5	VAC
7	KΩ

21	10
22	1
23	.1

[1] The logic is ground true. If any line is low with respect to the Digital Common output line when not in REMOTE, the FUNCTION or RANGE called for by the front panel pushbuttons may be confused.

[2] This line is open when REMOTE is not called.

The following schematics apply to the REMOTE 06 Option:

A12, Switch P.C. Board Schematic	37212-7-1
Option 06, Remote Control Schematic	37226-7-1

3.6.2 Digital Outputs, Option 05

For the data portion of the Remote Operation section, Option 05 provides parallel BCD outputs of all measurement data plus flag lines for PRINT command, INHIBIT RESET, $\overline{\text{START}}$, $\overline{\text{INHIBIT TRANS}}$, and BUSY conditions. All outputs are buffered, short-circuit proof and fully isolated. The logic levels are TTL/DTL compatible positive true.

"1" state (true) = +4 ±0.5 volts, 6 kΩ source.

"0" state (false) = 0 ±0.5 volts, 12 mA sink.

The standard BCD pin assignments are listed in Table 3.5 with connections for interfacing the Model 5103 Digital Printer to the Model 7110A Digital Multimeter. The connector J207 is an Amphenol 50-pin type 57-40500 and mates with P207 50-pin type 57-30500.

3.7 ACCEPTANCE TEST PROCEDURE

This test procedure permits functional checkout of the operating characteristics and specifications of the Model 7110A Digital Multimeter. The ambient temperature should be +23 ±1°C and the line voltage 115 V ac. Table 4.1 Calibration Equipment lists test equipment with sufficient specifications for this procedure.

3.8 SYSTEMS OPERATION

The Model 7110A is directly suitable for systems operation and may be custom modified to fit any operating configuration. With the standard Rear Input (08), Digital Outputs (05), and Remote Programming (06) options, the Model 7110A is able to perform in any data acquisition or computer-controlled system. The special systems options are described in the option portion of this manual. Interfacing the standard Digital Outputs (05) and Remote Programming (06) options to one particular system is explained in the following sections.

3.8.1 Computer Automated Test System (CATS) Interface

The Model 7110A Digital Multimeter is utilized by Systron Donner's Model 3600 Series Computer Automated Test System (CATS) to provide rapid and accurate digital multimeter measurements of signals from devices under test. The CATS Block Diagram, Figure 3.10, shows the position of the Multimeter in the test system as part of the Measurement/Analysis section. The device under test is coupled to the Multimeter via Adapter Unit, SD 3689, and the Connection Panel, SD 3681, containing the Multimeter Relay Tree Cards, SD 3648.

To couple the Model 7110A to the CATS Computer (PDP-11), an Interface Chassis has been devised called a Multimeter Driver, SD 3632. Interface bus buffers, input scan gates, output registers, and address cir-

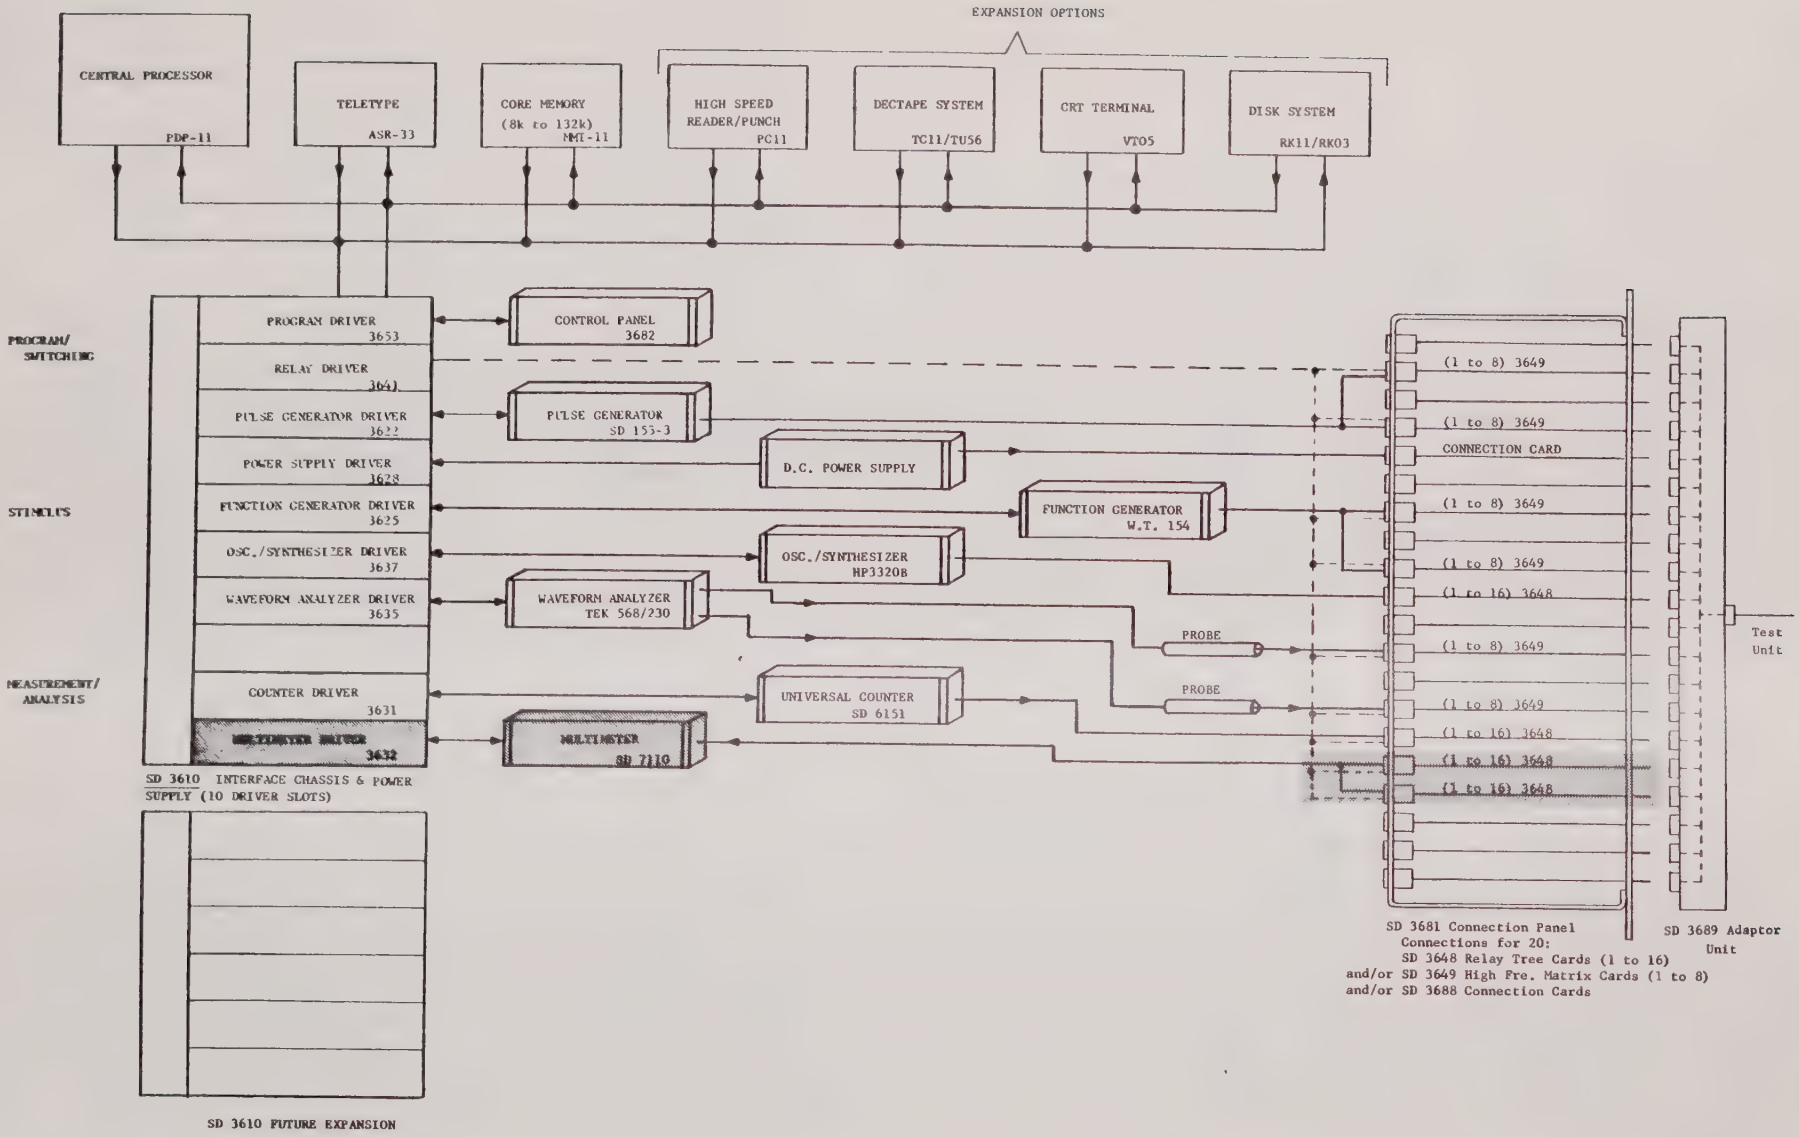

FIGURE 3.10 BLOCK DIAGRAM, CATS SYSTEM

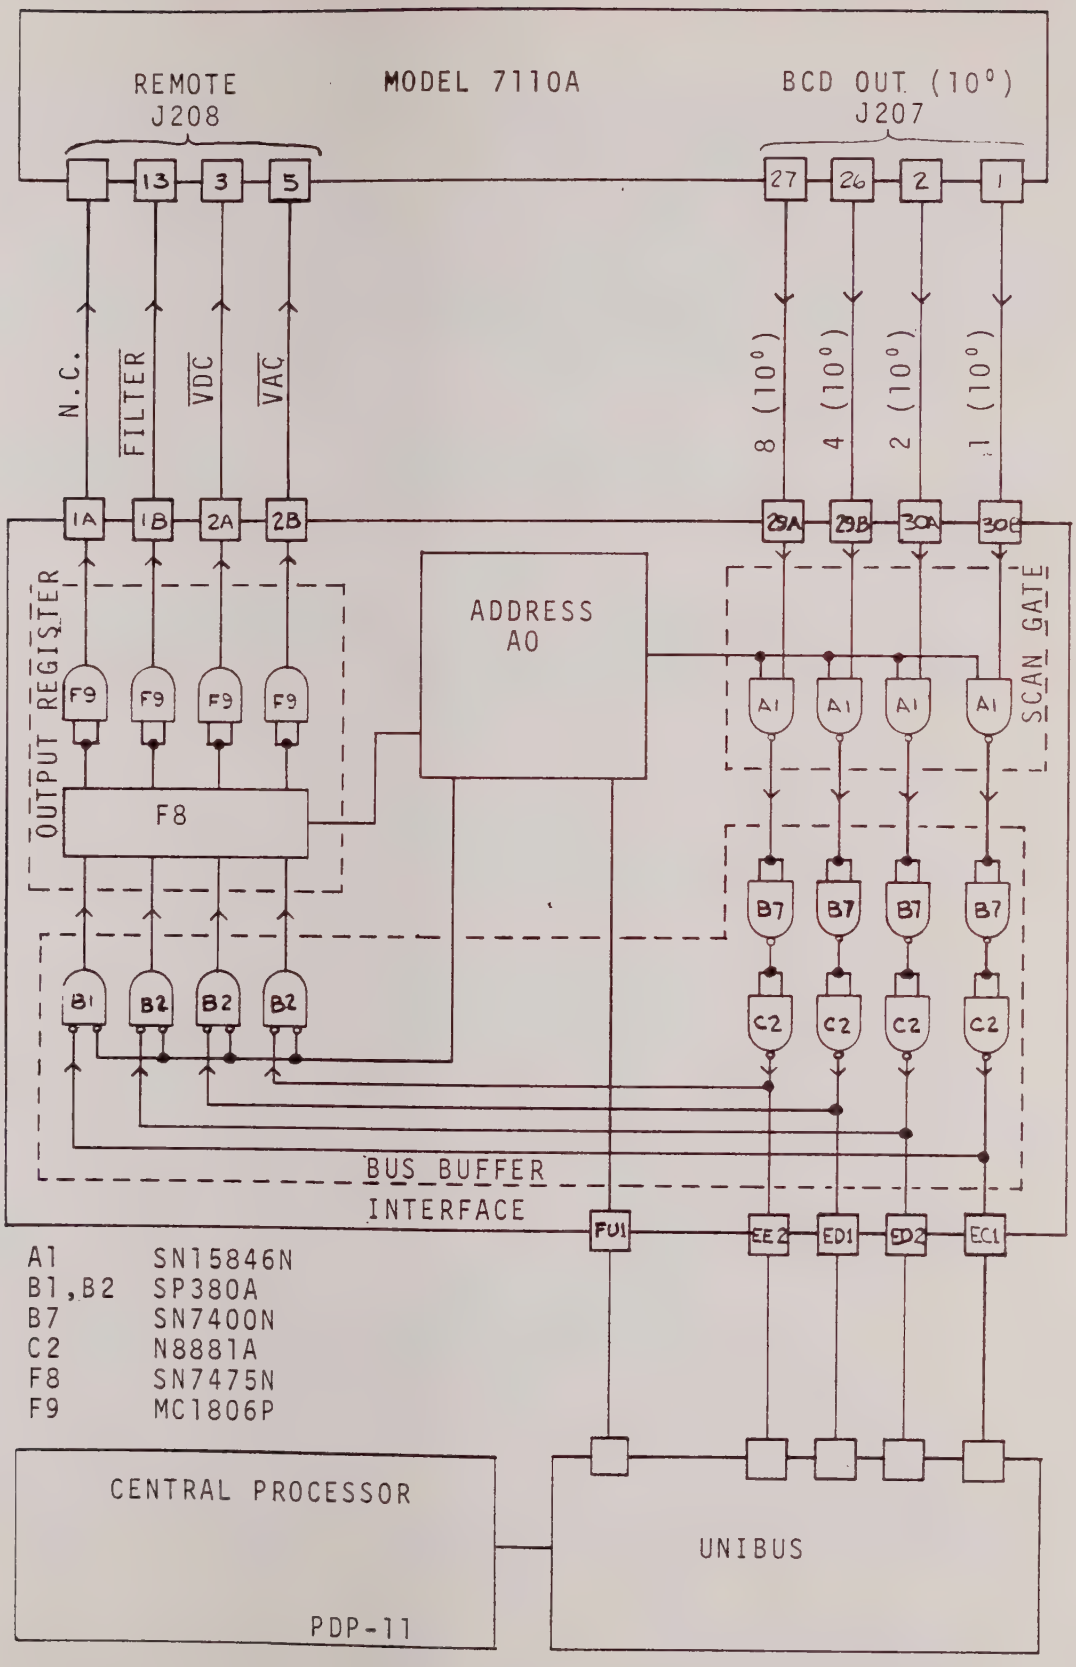

FIGURE 3.11 PARTIAL INTERFACE SCHEMATIC, CATS SYSTEM

cuitry comprise this basic SD 3632 Multimeter Driver. Figure 3.11 shows a simplified version of this driver and its position in relation to the UNIBUS and the DMM.

The Interface Bus Buffer section of the Driver board isolates the Scan Gate and Output Register from the UNIBUS lines terminated at EE2, ED1, ED2, and EC1. The control section of the Bus Buffer, NOT-AND Gates B1 and B2, accepts control signals from the UNIBUS Master and activates the proper QUAD LATCH, F8, and control gates, F9, in the Output Registe to select the associated Model 7110A REMOTE Function Line.

The Output Register acts as a buffer control for the Model 7110A BCD output. The Scan Gates are activated by the Address A0 when the UNI-BUS Master elects to read data from the DMM. In the Read-Data mode, the Address A0 strobes off Bus Buffer Bates, B1, B2, and A2 Output Re-gister F9, F8.

Standard BCD and Remote options are used in this interface system. The interface for any system may be built into the Model 7110A or optional nonstandard Remote and BCD configurations may be ordered.

3.9 APPLICATION NOTE

The lowest full scale resistance range on the Model 7110A DMM; namely, 1. KΩ with Option 08 installed, may be extended to lower full scale

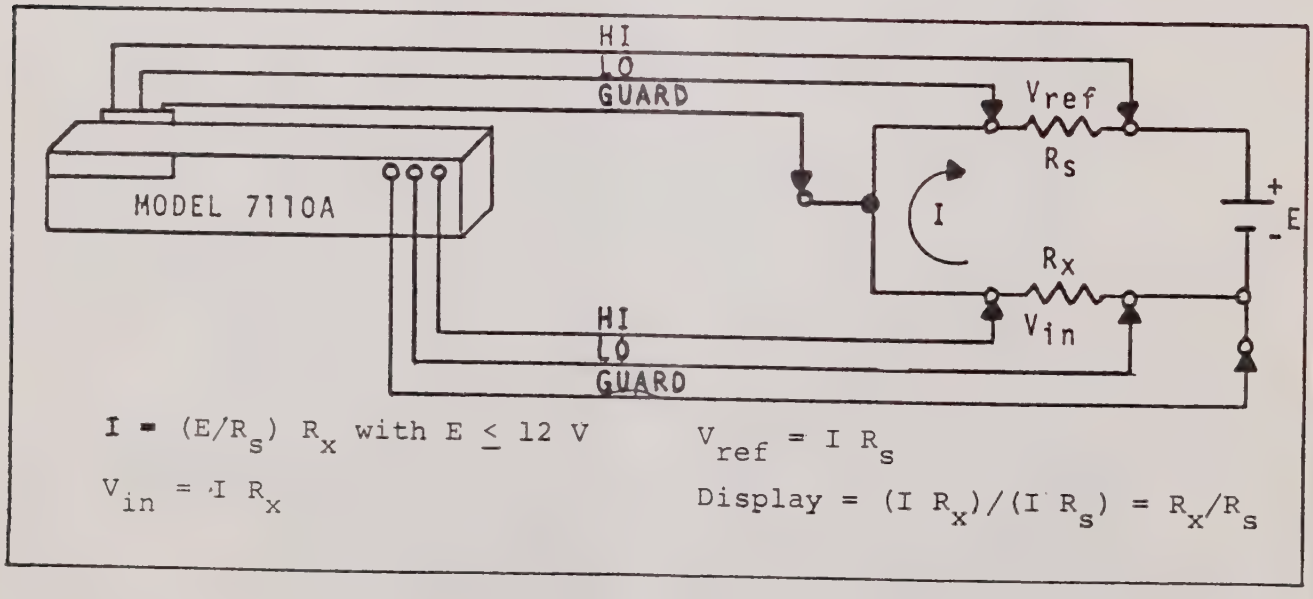

FIGURE 3.12 LOWER FULL SCALE Ω RANGE SETUP

resistance ranges with the use of the dc/dc RATIO operating mode. To accomplish this range extension, an external resistance standard (R_s) and a voltage source (E) are all the additional equipment needed. Select the RATIO FUNCTION and the .1 RANGE pushbuttons and connect the 7110A as shown in Figure 3.12.

Example: For 10 Ω full scale: Select the .1 RANGE. Let E = 12 and R_s = 1 kΩ. Then R_x = 10 Ω yields, R_x/R_s = 10/1000 = .01 kΩ full scale, etc.

CHAPTER 4
MAINTENANCE AND CALIBRATION

4.1 INTRODUCTION

This section contains instructions on how to maintain and calibrate the Model 7110A Digital Multimeter. Factory service, routine maintenance, printed-circuit board repair, and calibration are included.

4.2 FACTORY SERVICE

When the instrument requires service, the nearest Systron-Donner representative should be contacted. He can provide field service or arrange for factory returns when necessary. Address all inquiries on operation or application to your nearest sales representative; or, Sales Manager:

SYSTRON-DONNER CORPORATION
CONCORD INSTRUMENT DIVISION
10 Systron Drive
Concord, California 94518
Phone: (415) 676-5000
TWX: 910-481-9479
Cable: SYSTRONDONNER

Specify both model and complete serial number in all correspondence.

4.3 ROUTINE MAINTENANCE

A regular program for routine maintenance and inspection every twelve months is recommended for this unit. As part of these regular procedures, the instrument should be checked in the following manner:

1) Disconnect ac power and remove the top and bottom covers.
2) Make a thorough visual inspection of all wiring and cables.
3) Check for physical integrity of all components, loose solder connections, leakage of insulation compounds, and general physical damage. When a printed-circuit board contains integrated-circuit packages, ensure that all packages are firmly mounted. Never unnecessarily remove and replace a package.
4) Check all switches and connectors for loose or broken terminals, loose or sticking shafts, etc.
5) If the internal panel surfaces and components have an excessive amount of dust deposited on them, use a low-pressure stream of clean, oil-free air to remove the foreign material. After initial air cleaning, wash all analog printed-circuit boards and Mother board in a bath of distilled water. Place chassis and P.C. boards in a drying oven for 1 or more hours at 50°C to 70°C.

CAUTION

Do not clean printed circuit boards or small internal components with a stiff brush or solvents, since damage to the circuits may result. Also, a high-powered vacuum cleaner should not be used on small internal components.

6) Wipe the external surfaces of the instrument with a soft damp cloth to remove dirt, fingerprints and other foreign material.

7) Clean the polarizing filter window using only a soft cloth and warm soapy water: ABRASIVES OR SOLVENTS WILL DAMAGE THE FILTER. If desired, the filter may be removed for cleaning (remove trim and slide filter out of the end). The surfaces of the indicator tubes may be cleaned with a damp cloth at this time.

8) Perform the Calibration Procedure; if performance does not match or exceed the specifications listed in Chapter 1 of this manual, corrective maintenance is in order.

4.4 PRINTED-CIRCUIT BOARD REPAIR

When replacing integrated circuits or other electronic components soldered to printed-circuit boards, the procedures indicated below must be followed or damage to the board may result:

1) Determine by troubleshooting techniques, which integrated circuit or discrete component(s) has failed.

2) Remove the defective component(s) from the board by cutting the pins or leads with a small diagonal clipping tool. (Always remove and replace the entire component.)

3) Apply heat (40-50 W soldering iron) sparingly to each of the cut pins or leads and remove from the board; clean the hole(s) with a toothpick or solder suction tool.

4) Form the tinned leads of the replacement part and insert in the printed circuit holes; solder, then trim leads to extend 1/16-inch beyond the back surface of the board. (Use only 63-37 solder with maximum 1/16-inch diameter.)

5) Clean all dirt and solder-flux from the printed circuit traces by liberal application of isopropyl alcohol. Cleanse and dry analog P.C. boards as indicated in Section 4.3, paragraph 5.

4.5 CALIBRATION

WARNING

The WIRING and exposed metal parts of the GUARD are at signal or GUARD terminal potential. Insulated adjusting tools should be used throughout the calibration procedure, and especially when making the high frequency compensation adjustments on the A9, AC Converter board.

Calibration of the Model 7110A Digital Multimeter requires test equipment of equal or greater accuracy than the equipment listed in Table 4.1. The step-by-step calibration procedure which follows Table 4.1 should be performed in listed order since earlier steps may effect later ones.

TABLE 4.1 CALIBRATION EQUIPMENT FOR MODEL 7110A

Type	Required Characteristics	Suggested Equipment
1) Autotransformer	0-130 V ac	VARIAC; Model W8MT3VM, General Radio
2) Digital Voltmeter	.01%	Model 7004A Systron-Donner
3) Oscilloscope	1 mV/cm sensitivity	Model 533 w/Type W plug-in, Tektronics
4) DC Voltage Calibrator	.1 ppm accuracy, ±1 ppm linearity	Model 720A Kelvin-Varley Voltage Divider,
	0-1111.1110 V .1 ppm accuracy	Model 335A DC Voltage Standard, Fluke (2 units required to set up RATIO)
	±.001% of output +.5 µV, .2 ppm resolution	Model 750A Reference Divider, Fluke
	Traceable to NBS	Model 121 Standard Voltage Reference, Eppley Laboratory
5) AC Voltage Calibrator	0.100000 mV to 1099.999 V, ±.05% of setting +0.005% of range +50 µV	Model 745A AC Calibrator & 746A High Voltage Amplifier, H.P.
6) Resistance Standard	.000001 kΩ-10 MΩ, error < 50 ppm	Model RS 925C Decade Resistance Standard, ESI or 1063A

4.5.1 Preliminary Checks

Check the RANGE and FUNCTION combinations listed in Table 4.2 for proper annunciator and decimal point indication.

TABLE 4.2 PRELIMINARY CHECKS

1000 RATIO	RATIO	abc.def
10,000 RATIO	*	abcdef
TEST	-	ab.cdef
10,000 TEST	*	ab.cdef

Check the SAMPLE RATE control for a stationary reading in the HOLD position; an adjustable sample rate from 1 sample per 10 seconds to 10 samples per second in the variable position; and in the most counterclockwise detent position, a much faster rate than in the adjustable range. Note, that in the HOLD-SINGLE position, the pushbutton will provide a single reading when depressed.

* Indicates invalid RANGE & FUNCTION selection.

4.5.2 Power Supply Voltage Adjustment

Remove the calibration cover and set A6 or A7 on an extender board. The negative floating power supply for the Ω CURRENT SOURCE is measured with Item 2, Table 4.1 across A10C6 or between A7(1,A) and A7(3,C). The level should be -17.5 to -18.0 V dc. This supply is adjusted by removing A10 jumpers 12 and 13. Removing jumper 13 lowers the voltage about .7 V, removing jumper 12 raises the voltage about 0.5 V.

The positive floating power supply for the current source is measured across A10C5 or between A7(1,A) and A7(2,A). The level should be +17.2 to +18.3 V dc.

The positive and negative main power supplies are measured between A6(22,Z) and A6(21,Y), and between A6(22,Z) and A6(20,X) respectively. The value of voltage should be within 1 V of 20 V. Adjustments are made by shorts which can be added or removed from around A6(R28,R29,R33,R34), and provide a total range of adjustment greater than 8%. Voltage is raised by removing shorts or lowered by adding shorts.

With the SIGNAL INPUT HI and LO terminals shorted, the VDC FUNCTION selected, and the 10 RANGE selected, the voltage difference between terminals 29 and 30 should be less than 0.5 mV. Adjust this voltage with A10-R28.

4.5.3 VDC Adjustments

See schematics and assemblies for boards A2, A3, A4, and A6. Test equipment includes Items 2 and 4 of Table 4.1. Remove extender, replace cover.

Check and reset, if required, the reference inverter amplifier balance. Technique: Set the FUNCTION switch to RATIO. Short the HI and LO EXT REF INPUT on the rear panel. Short A6TP4 to A6TP1 and connect a voltmeter between A6TP3 and A6TP1. Adjust RATIO ZERO to obtain a reading as near zero as possible (less than 100 μV). Alternatively, the Model 7110A input and detection circuitry can be used as a null meter for such measurements by selecting the .1 RANGE on RATIO function, shorting the input and adjusting the mV ZERO panel control to give a flashing polarity indication, then, connecting the HI terminal to A6TP3 and adjusting RATIO ZERO to give the flashing sign and a large meaningless number.

Adjust the external reference buffer amplifier offset by removing A6TP4 to A6TP1 short and connecting A6TP4 to the HI INPUT terminal. Set the instrument to .1 VDC range. With a short applied between the HI and LO RATIO INPUT, adjust EXT REF ZERO to read the least possible voltage (less than 30 μV).

Adjust the external reference buffer gain and common mode rejection by connecting a 10 V dc standard voltage to the RATIO INPUT, and the HI input terminal of the instrument to A6TP4. Alternately connect the high, then the low terminal of the external reference supply to the SIGNAL INPUT LO connection of the

instrument and alternately adjust GAIN and CMR to give a 10.0000 reading. Continue this operation until no further change in reading is noted when the connection is changed. This adjustment can also be made by connecting one standard voltage source to the SIGNAL INPUT, and a second standard voltage source to the RATIO INPUT. Set FUNCTION to RATIO, RANGE to 10; then alternately switch the SIGNAL INPUT LO from RATIO INPUT HI to RATIO INPUT LO, making the adjustments for GAIN and CMR as described above to obtain a reading of 1.00000 RATIO.

The temperature coefficient of the internal reference voltage supply is changed by the setting of A6R11. Adjustment of this control is carried out initially with a warm air gun supplying heat to raise the temperature of all components an equal amount. If the instrument is set to measure a stable external voltage source; and the A6 board heated uniformly by a warm air source, near 70°C; and if the instrument reading increases with the temperature; then, the TC of the power supply is negative. To secure a more positive coefficient, the current in the reference diode should be increased. This can be achieved by counterclockwise rotation of the TC control.

Check and reset, if required, the Integrator Zero detector adjustments. Technique: Remove the A3 Input Amplifier from the instrument to ensure a zero current into the A4 Integrator Zero detector board. Measure the output voltage of the integrating amplifier in the HOLD mode with a sensitive voltmeter, and adjust the INT ZERO to give a reading less than 100 μV. (The left-hand end connection of A4C8 is a convenient place to make connection to the output of the amplifier and there is a nearby ground terminal.) Then adjust DET ZERO to give flashing ± sign. Reinstall the Input Amplifier assembly and allow the unit to come to a stable temperature. Short the instrument input and select the .1 VDC range. Adjust the front panel mV ZERO to give a flashing + or - sign.

Select the 10 VDC range and alternately apply + and -1 mV. Adjust the THRESHOLD control and the variable differential capacitor, A6C3, to give a + or - 10 count reading. Recheck with an input short for a flashing + or - sign and a zero or 1 reading. Slight Adjustment of the DET ZERO is necessary to achieve the flashing sign. This adjustment may be made with the board on an extender or in the unit. To adjust the symmetry with A6C3, the board must be removed from the instrument during which time a small change is made in the capacitor setting. The board is then reinstalled to test. Wait approximately 1 minute for the unit to stabilize if the operation of turning the instrument off, removing the A6 board, adjusting A6C3, reinstalling A6, and turning the instrument back on, is carried out quickly. The balance between the two polarity readings should be made as equal as possible since it will become more sensitive to unbalance when low-voltage external reference voltages are used.

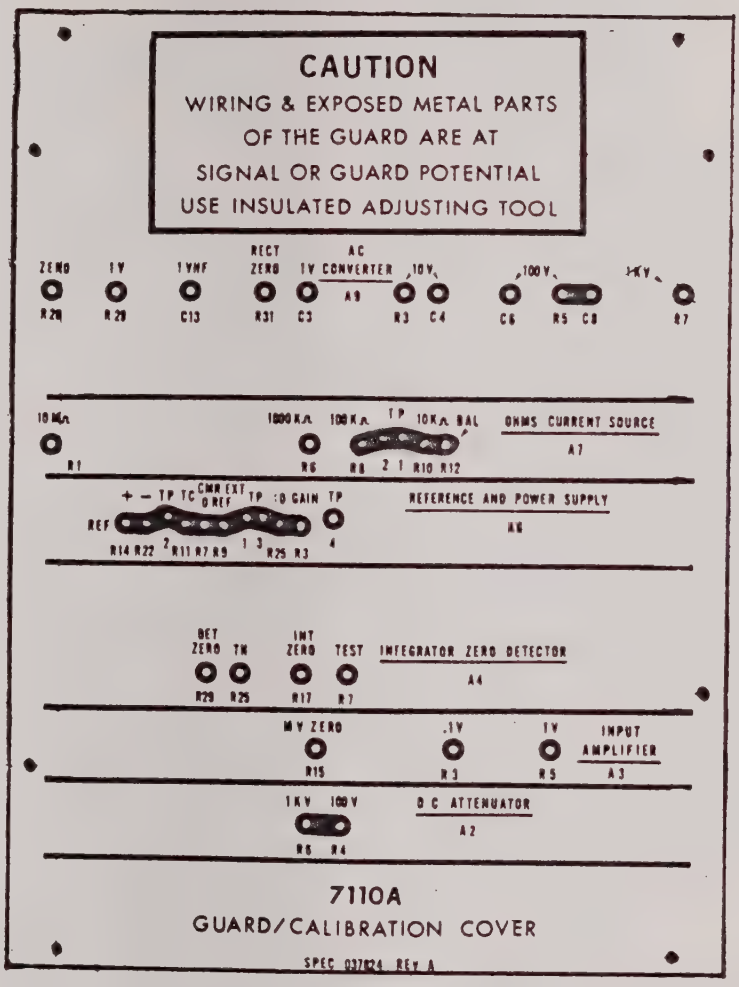

FIGURE 4.1 MODEL 7110A GUARD/CALIBRATION COVER #037824

FIGURE 4.2 INTERIOR TOP REAR VIEW OF MODEL 7110A

Press the TEST FUNCTION button and adjust the TEST control, A4R7, for a reading of +10.0000 ±1 digit. A4R8 may need to be shorted or have a short removed if component aging has caused A4R7 to require setting at an end.

Set the instrument on 10 VDC and apply +10.0000 V dc. Adjust +REF, A6R14, to obtain a reading of +10.0000 VDC. Apply -10.0000 V dc and adjust -REF, A6R22, for a reading of -10.0000 VDC.

Set the instrument on 1 VDC and apply +1.00000 V dc Adjust 1 V, A3R5, to obtain a reading of +1000.00 mVDC. Check for equal magnitude with -1.00000 V dc applied.

Short the input and select .1 VDC. Check for alternating polarity signs and readjust the front panel mV ZERO control if required. Use mV ZERO, A3R15 if coarse zero is needed. Remove short and apply +.100000 V dc and adjust .1 V, A3R3, to obtain a reading of +100.000 mVDC. Check for equal magnitude with -.100000 V dc applied. 5-count deviations are not out of specification and the stability of the ZERO is generally the reason for nonequality of the .1 VDC setting.

Check the effect of the various SAMPLE RATE switch positions on the reading with + and -0.100000 V dc applied. The reading should not change more than 2 digits between the slower rates and the fastest rate.

Set the instrument on 100 VDC and apply +100.000 V dc. Adjust 100 V, A2R4, to obtain a reading of +100.000 VDC.

Set the instrument on 1000 VDC and apply +1000.00 V dc. Adjust 1 kV, A2R6, to obtain a reading of +1000.00 VDC.

4.5.4 Auto Range Adjustments

Select 10 VDC on the front panel and apply successively higher voltages (10, 11, 12, 13, 14, 15, 20, 30, 40, and 50 volts) of both polarities. Observe that the reading does not decrease with an increase in input voltage. For inputs with magnitude greater than 13 V dc, the reading should be somewhat greater than 13.0000. If the unit fails this test, the input amplifier should be analyzed for faulty elements.

With the unit in AUTO RANGE and VDC FUNCTION, apply various voltages of either polarity in the range 0-1000 V dc, and observe that valid ranges are selected. No number greater than or equal to 130000 should be observed as a final reading, and no number less than 010000 should be observed except on .1 VDC.

4.5.5 KΩ Adjustments (Option 03)

Install A7 on a printed circuit extender board. Connect a calibration standard 10 MΩ resistor, Item 6 of Table 4.1, between the front panel Ω CURRENT SOURCE HI and LO terminals and connect the SIGNAL INPUT HI and LO terminals to the standard's voltage terminals. Set FUNCTION switch to KΩ and RANGE switch to 10,000.

Connect a shorting jumper from the lower end of A7R11 to A7TP2. Adjust the BAL, A7R12, control to achieve minimum reading. Remove short.

The RVL-3 has been factory adjusted and should be recalibrated only if it has been replaced or has drifted out of specification. Set the 10 MΩ, A7R1, control to its midpoint and add or remove shorts around resistors A7A3 (R6, R5, R4, R3, R2, and R1) to give a reading within ±100 digits of 10.0000 MΩ. Shorting of A7A3R1 should reduce the reading about 75 digits. The other resistors in the set cause changes progressively greater by a factor of 2. After the correct setting of shorts close to 10.0000 MΩ, adjust A7R1 to give a reading of 10.0000 MΩ. Reinstall the A7 board in the unit and attach the Guard/Calibration cover.

Connect in succession, calibration resistors of 1000.00 kΩ, 100.000 kΩ, and 10.0000 kΩ to the input; and with the instrument on the appropriate range, adjust 1000 KΩ, A7R6; 100 KΩ, A7R8; and 10 KΩ, A7R10.

4.5.6 AC Adjustments (Option 02)

Install A9 on a printed circuit extender card and select 1 VAC. Apply 0.50000 mV at 200 Hz to the SIGNAL INPUT HI and LO terminals with Item 5, Table 4.1 standard. Connect the oscilloscope, Item 3, Table 4.1, to the junction of A9U1-pin 6, A9R11, A9CR3, and A9CR4. Adjust RECT ZERO, A9R31, to obtain a symmetrical waveform; time high equal to time low. Disconnect oscilloscope.

Apply 10.00 mV at 200 Hz, and adjust ZERO, A9R28, control to give a reading of 0.01000 VAC. Increase the input to 20.00 mV at 200 Hz and note whether or not the reading increases to approximately 0.02000 VAC. If not, apply 10.00 mV at 200 Hz again and find a second position on the potentiometer which will give a 0.010000 VAC reading. Recheck again with 20.00 mV at 200 Hz applied. For finer adjustment, reduce the input to 1.00 mV, reset ZERO, A9R28 slightly, and check with a 2.00 mV input.

Short the input resistor A9R1 (center of board) and apply an input of 0.50000 V at 200 Hz and note the reading. Change the frequency to 100 kHz and adjust 1 V HF, A9C13, to give the same reading. Scan the frequency band between these two frequencies to determine that the response function does not deviate by more than 20 counts. Component location and the values of A9C12 and A9C19 may need to be changed to achieve the necessary specifications. Remove the short.

Install the board back in the unit and replace the Guard/Calibration cover. Apply 1.00000 V at 200 Hz and adjust the 1 V, A9R29, potentiometer to give a reading of 1.00000 VAC. Change frequency to 100 kHz and adjust 1 V capacitor, A9C3, to give a reading of 1.00000 VAC. Check at various frequencies between 200 Hz and 100 kHz to determine that the response is within 80 digits of 1.00000 VAC. The reading at 100 kHz may be adjusted finer by moving some components, A9R1 and A9R8, away from the board and other components.

Select 10 VAC and apply 10.0000 V at 200 Hz. Adjust 10 V, A9R3 to give a reading of 10.0000 VAC. Change frequency to 100 kHz and adjust the 10 V capacitor A9C4 for a reading of 10.0000 VAC. Check the response at intermediate frequencies for a maximum deviation less than 80 digits. Changing the distributed capacitance between A9R34 and ground can alter the midband response.

Select 100 VAC and apply 100.000 V at 200 Hz to the input. Adjust the 100 V, A9R5, potentiometer for a reading of 100.000 VAC. Change the frequency to 100 kHz and adjust the 100 V, A9C6, capacitor for a reading of 100.000 VAC. Scan the intermediate frequencies and check for a maximum deviation less than 80 digits. Plot the response function to help in determining which way component values need changing.

Select 1000 VAC and apply 750.00 V at 200 Hz. Adjust 1 kV, A9R7, for a reading of 0750.00 VAC. Change frequency to 100 kHz and adjust 1 kV, A9C8, for a reading of 0750.00 VAC. Check the response at frequencies between 200 Hz and 100 kHz for a deviation less than 60 counts. For excessive deviation, make a compromise adjustment of A9C8 or change the value of A9C2, A9R15, or A9R33.

4.5.7 AC Adjustments (Option 10)

Visually inspect the converter. Insert converter into socket A9 of 7110A DVM, if not already installed. Select VAC and apply ≈ 50% FS dc voltages to the Model 7110A DMM on all AC ranges (1, 10, 100, 1000 V). See whether the converter functions properly on these ranges. Repeat with opposite polarity of dc voltage. Put GUARD/CALIBRATION cover on and wait for the temperature to stabilize (≈ 30 minutes).

For the dc setting adjust AMP ZERO (R10) with the Model 7110A in 1 VAC. Apply 0.01 V from DC Standard to input of the Model 7110A. Adjust AMP ZERO so that the two readings obtained by applying 0.01 V with both polarities alternately are within 20 counts. Check at ±1 V dc input. The two readings should be within 50 counts. Set 1 V (R14) to center the readings around 100,000 counts. Adjust CONV ZERO (R15) with the Model 7110A in 1 VAC. Apply 0.01 V from DC Standard to input of the Model 7110A. Adjust CONV ZERO so that the two readings obtained by applying 0.01 V with both polarities alternately are centered around 1000 counts. Adjust 1 V (R14) with the Model 7110A. Adjust 1 V so that the two readings obtained by applying 1 V with both polarities alternately are centered around 100,000 counts. The following end results should be with the Model 7110A in 1 VAC range:

Input (V)	Reading (Counts)
+.01	1000 ±15
-.01	1000 ±15
+1	100,000 ±25
-1	100,000 ±25

Adjust 10 V (R3) with the Model 7110A in 10 VAC. Apply 10 V from DC Standard to the input of the Model 7110A. Adjust 10 V so that the two readings obtained by applying 10 V with both polarities alternately are centered around 100,000 counts. Adjust 100 V (R5) with the Model 7110A in 100 VAC. Apply 100 V from DC Standard to the input of the Model 7110A. Adjust 100 V so that the two readings obtained by applying 100 V with both polarities alternately are centered around 100,000 counts. Adjust 1000 V (R8) with the Model 7110A in 1000 VAC. Apply 500 V from DC Standard to the input of the Model 7110A. Adjust 1000 V so that the two readings obtained by applying 500 V with both polarities alternately are centered around 50,000 counts. Check all ranges and readjust if necessary. If the dc setting is correct, continue with the following ac adjustments.

Use the following procedure for Ranges/Capacitors 1 V/A9C1, 10 V/A9C2, 100 V/A9C4, 1000 V/A9C6, in that order. Apply 100% (50% on 1000 V range) FS voltage from AC Standard. Note reading at 50 Hz. Adjust C to get the same reading at 10 kHz. (Caution, these capacitors are at input voltage. Use insulated tool). Check all ranges. If the two readings are still the same continue, otherwise, start VAC procedure again. On the 1 V range find the frequency under 10 kHz at which the characteristics peak. Compute the difference of the readings at 50 Hz and at peaking. (Peaking usually occurs around 2 kHz). By adjusting 1 V (A9R14) set the reading at 1 V/50 Hz input to:

Original reading at 50 Hz - (Difference/2).

Check overall performance of the device according to the table below.

Full Scale on ranges 1 V, 10 V, 100 V	
FREQUENCY	ERROR
50 Hz - 10 kHz	±120
10 kHz - 20 kHz	±470
20 kHz - 100 kHz	±1440
100 kHz - 300 kHz	±3000

50% Full Scale on 1000 V range	
50 Hz - 10 kHz	±85
10 kHz - 20 kHz	±330
20 kHz - 100 kHz	±950
100 kHz - 300 kHz	±1700

1% Full Scale on 1 V range	
50 Hz - 10 kHz	±50
10 kHz - 20 kHz	±200
20 kHz - 100 kHz	±500
100 kHz - 300 kHz	±500

4.5.8 Remarks

During the calibration procedure, it is helpful to occasionally check some of the original setup steps since there is some influence on the earlier adjustments.

4.5.8 Remarks (Cont'd)

WARNING

Exercise care during high voltage calibration since the adjusting capacitors are at the input potentials and these are lethal values on the higher ranges.

If the unit contains options not described in this chapter, any necessary calibration procedures will be found in Chapter 6 with the option description.

CAUTION

CLEANING SOLVENTS MAY DAMAGE ALUMINUM ELECTROLYTIC CAPACITORS

Aluminum electrolytic capacitors are inherently susceptible to attack by halogenated hydrocarbon solvents. Industry standards, such as EIA RS-395 and Military Specification MIL-C-39018, caution against their use. Specifications of many major O.E.M. customers specifically forbid the use of halogenated cleaning materials on aluminum electrolytic capacitors.

However, some users will clean printed circuit boards carrying aluminum electrolytic capacitors with trichloroethylene, Freon, or other halogenated solvents. A bath in any of these cleaning or degreasing compounds can create serious problems. Should these solvents seep into electrolytic capacitors around their seals, they will attack the internal section and the resultant corrosion will cause the capacitors to fail after a few months.

Compounds containing halogenated hydrocarbon solvents are popular because of their effective cleaning properties and the ease and safety with which they can be handled. Customers may therefore insist on subjecting aluminum electrolytic capacitors to cleaning in these materials. Where this situation exists, the customer should order special units with a supplemental epoxy barrier over the end discs or headers.

As an alternate to the special units, customers should consider inserting electrolytic capacitors on their wiring boards after the boards have been subjected to cleaning with whatever halogenated solvent they may wish to use.

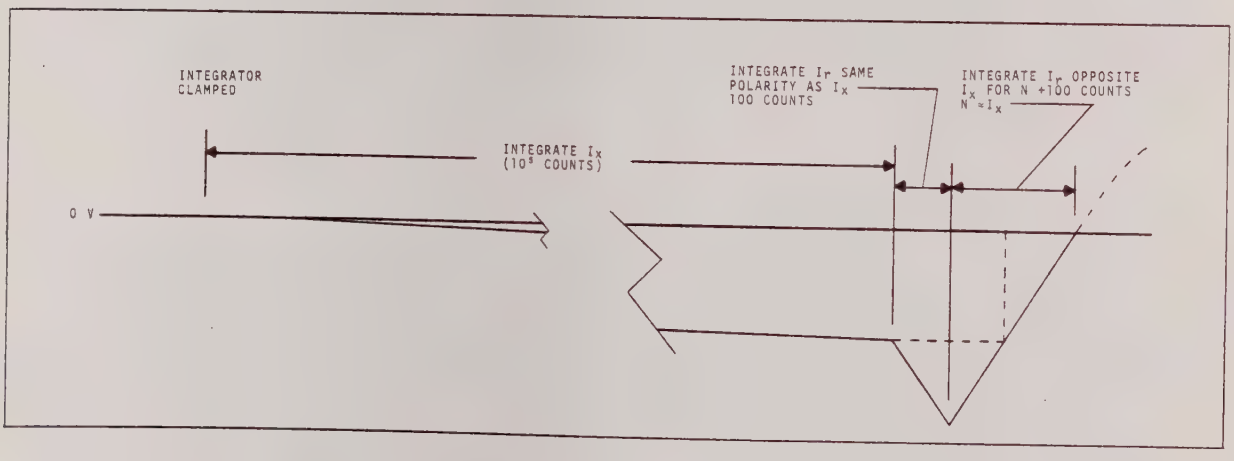
CHAPTER 5
CIRCUIT DESCRIPTIONS, DRAWINGS, AND PARTS LISTS

5.1 INTRODUCTION

This Chapter provides circuit descriptions for the various assemblies in the Model 7110A Digital Multimeter. A general analog to digital description precedes the specific circuit descriptions with the numbered assemblies following the "A" number sequence.

5.2 ANALOG TO DIGITAL CONVERSION

The conversion of the analog input, the unknown voltage, to a number proportional to the input is carried out by the circuitry of the Integrator Zero Detector, A-D Control Logic, Reference, and the Digital Counter. The cycle of conversion is divided into four time periods, the integrator clamped, integrating I_X, integrating a current of same polarity as I_X, and integrating a current of polarity opposite to that of I_X.



5.1 ANALOG TO DIGITAL CONVERSION CYCLE

The cycle starts with the digital counters set to 100,000 and not counting, the integrator clamped, and the unknown current coupled into the integrator. A signal from the digital count and control section combined with the 6 MHz clock signal triggers an element of the A-D Control Logic which gates the clock on to the digital counter and turns the integrator clamp off.

While the counter accumulates 10^5 counts, I_x will be integrated and the polarity of the integrator output continuously monitored. A pulse from the counter corresponding to 10^5 counts, named Full Scale, triggers an element of the A-D Control Logic, which switches I_x from the integrator to signal low, stores the polarity of the integrator at the end of the period, and connects a reference current to the integrator which will cause the output of the integrator to move from zero output in the same direction as the final output was displaced from zero.

After the digital counter has accumulated an additional 100 counts, a pulse, named Complement, triggers an element of the A-D Control Logic which in turn changes the polarity of the reference current, enables the digital elements of the zero detections circuitry, and selects the appropriate threshold voltage for the comparator corresponding to the determined polarity. When the counter has accumulated an additional 100 counts, the output of the integrator is equal to its value at the time of Full Scale pulse, transient switching pulses have disappeared and the integrator output is approaching zero voltage in a linear fashion, at a constant rate. After this 200th count, the output of the 1×10^2 stage in the count chain is reconnected to the subsequent stages, (it was disconnected at Full Scale pulse), an integration will continue until zero is detected, causing the clock to be gated off. The number stored in the counter at this time is proportional to I_x. After zero detection, the reference current is switched off, I_x is switched back into the integrator, the integrator clamp is turned on, and the A-D Control Logic is returned to the state to receive the next starting signal from the digital count and control section.

5.3 CIRCUIT DESCRIPTIONS

Each section in this Chapter contains assembly information composed of a circuit description, an assembly drawing, a schematic, and a parts list. Only standard assemblies are described. The Block Diagram, final assemblies and final assembly parts list preceed the "A" numbered assembly packages. Table 5.1 Drawing Index Information lists the contents of this chapter.

The sections are numbered in a sequence as follows:

EXAMPLE: A2-1

A2 — Assembly

-1 — Page number of the assembly

Each column in the parts list provides specific information relating to the listed parts as follows:

1) REFERENCE DESIGNATION: P.C. assemblies are listed in numerical order. Reference numbers applicable to these assemblies are listed in alpha-numeric order.

2) NAME OF COMPONENT AND DESCRIPTION: Component names and specifications are provided in these columns and include: value, tolerance, wattage rating, working voltage, construction, etc.

3) MANUFACTURER'S CODE: H4-2 Federal Supply Code numbers are listed to identify component manufacturers. A Manufacturer's Index is provided in Chapter 7, Appendix A, for cross-reference.

4) MANUFACTURER'S PART NUMBER: True manufacturer part numbers are listed in this column.

5) NUMBER OF TIMES USED: This quantity, appearing after an item entry, indicates the number of times the component is used in that assembly.

6) S-D STOCK NUMBER: The Systron-Donner stock number is listed in this column.

CIRCUIT DESCRIPTION
A1, GUARDED CONTROL CIRCUIT
SCHEMATIC #037168-7-1

The A1 board in the Model 7110A has nine reed switches which are mounted on terminal lugs and positioned close to nine sets of magnetic pole pieces which project through the front plate of the guard structure. Through the operation of these nine switches the other reed relays on the analog circuit boards are set in the arrangement required for a particular range. The table shows which of the guarded control switches are closed on each range and function along with those on other boards which are also closed. Some of the entries in the table are the symbol ✓ which indicates that the switch is closed, but non-functional, for the function selected. These reeds are all on the option boards, the kilohms, current source, and the ac to dc converter board.

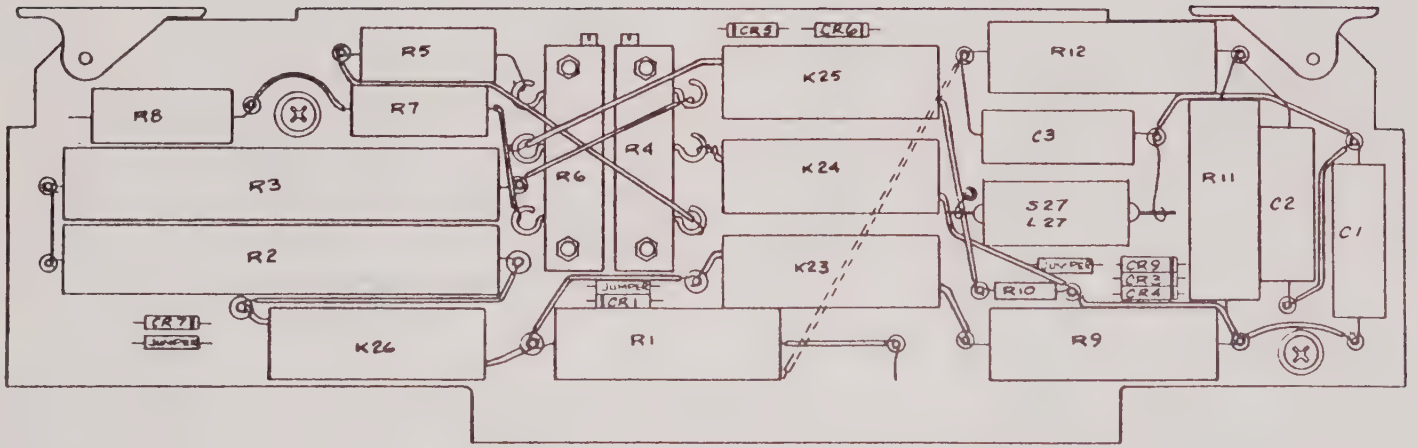
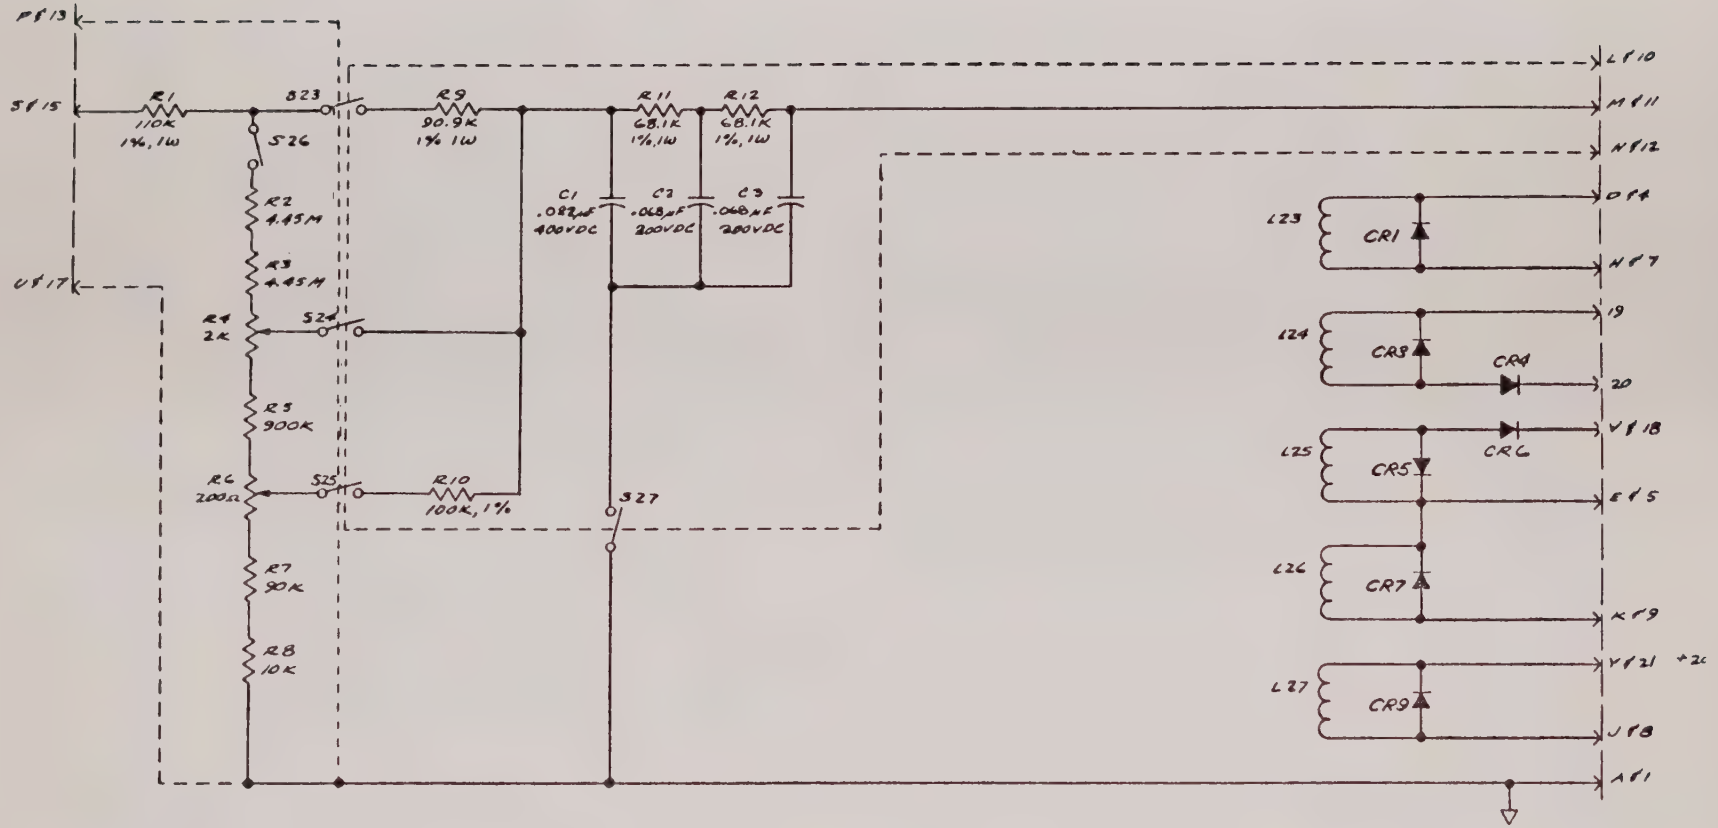
CIRCUIT DESCRIPTION
A2, DC ATTENUATOR & FILTER
SCHEMATIC #037279-7-1

The dc attenuator is assembled with a set of precision resistors having a low-temperature coefficient and a low-voltage coefficient. There is no attenuation of the input voltage on the .1, 1, and 10 volt ranges. The relays used for the switching are special assemblies having very-low, self-generated thermal emfs. The resistors in series with the input amplifier, A2R1, A2R9, A2R11, and A2R12, are precision types selected for low-thermal emf generation, and they have a combined power rating sufficient to handle the dissipation due to a maximum rated input voltage when the instrument is on one of its more sensitive ranges. The capacitors, A2C1, A2C2, and A2C3, are connected by A2S27 to the signal common to provide filtering of normal mode signals. Filtering is about 25 dB at 50 Hz and increases at about 12 dB per octave. A2R4 is adjusted to obtain correct calibration on the 100-volt range and A2R6 is adjusted for the 1000-volt range.



A2, DC ATTENUATOR & FILTER ASSEMBLY #037279-4-1 REV D



NOTE:

1. ALL DIODES - IN4151
2. K23, 24, 25 & 26 - 37461-4-1
3. S27 - MR106; L27-U32P.

CIRCUIT DESCRIPTION
A3, INPUT AMPLIFIER
SCHEMATIC #7-03749501

The input amplifier, A3, board, transforms the input voltage into a current which is used to charge the capacitor in the integrator. It includes range changing resistors so that the full-scale output current can be generated with either 10 volts, 1 volt, or 0.1 volt input, Separate supplies for the amplifier element are provided so that all the load current, I_X, will flow through the selected feedback resistors A3R2 through R6. The gain of the amplifier element is very high so that the voltage between the two input terminals will approach zero and thus, the voltage drop in the feedback resistors will be nearly equal to the input voltage.

The nominal values of A3R2 through R6 are 100,000 Ω on the 10 volt scale, 10,000 Ω on the 1 volt scale, and 1,000 Ω on the .1 volt scale. The nominal value of I_X at full-scale is 100 µA. The input stage of A3 is a differential amplifier. It consist of a dual JFET A3Q1, the constant current source A3Q7 and an operational amplifier A3U1. To obtain very-low drift with temperature and time, A3Q1 is temperature compensated by potentiometer A3R11. After factory calibration of A3 the settings of A3R11, T.C., should be adjusted ONLY in case of changing A3Q1. The output of A3U1 drives a two-stage complementary type amplifier which has a very high output impedance and,thus, isolates the input of the multimeter from the switching transients associated with analog-to-digital conversion.

As an example of the operation of these elements consider the case when 100 µA flows into the output terminal A3R2. A3Q5 will be conducting and about 1.0 volts will be developed across A3R36, the base of A3Q5 will be about 1.6 volts above the -19 volt supply, and there will be a collector current of about 120 µA in A3Q3. Under these conditions the drop across A3R31 will be about 4.4 volts and the output of the amplifier at the base of A3Q3 will be about 5.0 volts. All paths through this circuit from R&14 to P&13 pass through A3R2 and R6, and the only current is the load current. For current out of the assembly A3Q2 and A3Q4 are on.

The power for the amplifier is supplied from a separate triple shielded winding on the power transformer, the rectifiers and main filter capacitors are in a guarded shield on the Analog Mother Board, and the regulator is on the A3 plug-in board with the other elements of the amplifier.

Clamping circuits to protect the amplifier from over-range voltages include A3CR1 and A3CR2 directly across the input-terminals and A3CR3, 4,5,6,VR1, and VR2 from the output of the operational amplifier to the input of A3Q1. When the output of the operational amplifier has a magnitude greater than 7.5 volts, either A3VR1 or A3VR2 will breakdown and conduct current through A3CR5 or A3CR6 respectively; and,when the magnitude of the voltage across R20 exceeds about .6 volts, then A3CR3 or A3CR4 will conduct current into the amplifier input. This increas-

ed current will cause a voltage drop in the series resistance elements between the amplifier input and the instruments HI input terminal. These resistance elements can sustain a 1 kV voltage drop without deleterious effects. The resistor network, A3R25,26 and 27 in conjunction with the front panel mV ZERO Pot. allow circuit adjustment for trimming any offset voltage, which might appear at the input of A3Q1. Coarse zero is accomplished by adjusting mV ZERO, A3R15.

CIRCUIT DESCRIPTION
A4, INTEGRATOR AND ZERO DETECTOR
SCHEMATIC #7-03762901

The A4 assembly performs the following functions: switching the unknown and reference currents, integrating the reference currents with respect to time, and comparing the output of the integrator at various times during the cycle with its output at the beginning of a measurement cycle. The signal inputs to this assembly are: the current proportional to the unknown voltage, named I_X, the positive and negative reference voltages, and the negative true control signals named $\overline{\int}$, $\int(+E_r)$, $\int(-E_r)$, $\int E_x$, $\overline{\int E_x}$. There is one output signal, from the zero detector, which is connected to the A-D Control Logic.

A4Q1 is on when terminal J, $\overline{\int E_x}$, is low and the unknown current, I_X, is shunted to ground. A4Q3 is on when terminal H, $\int E_x$, is low and the input unknown current is conducted to the input of the integrator. A4Q14 is on when terminal 2&B, $\int -E_r$, is low and conducts current from the integrator to the negative reference supply. A4Q15 is on when terminal 1&A, $\int +E_r$, is low and conducts current into the integrator from the positive reference supply. The combination A4 (R9 + R8 + R7) determines the magnitude of the reference current. A4Q8 is on when terminal F, $\overline{\int}$ is low and clamps integrator A4U1 to make the output voltage equal to the input voltage (nearly zero), and to set the initial conditions for the integration function to follow. This clamp is on from the end of one measurement cycle to the beginning of the next cycle.

Integration of the unknown starts when $\overline{\int}$ goes to the false state, high. The clamp on the integrator is turned off and A4C8 is charged by the unknown current with pin 6 of A4U1 going either positive or negative in response to this current. A positive signal out of the integrator and into the comparator A4U2 will result in a high output at terminal 9 to drive the following logic.

A fraction of the reference voltage is coupled into the reference side of the comparator through A4R15, A4R25, and A4R24. This voltage is adjustable to set the zero of the circuit. A4C3 serves as a means to adjust the symmetry of the threshold and is set to a condition that results in equal readings when small input signals, about 10 digits in value, are applied.

A4VR1 and A4VR2 are used to derive power supply voltages for the operational amplifier and the comparator. The INT. ZERO adjustment is made with a short on the input by measuring the output of the integrator with a voltmeter, and adjusting the control to obtain less than 20 μV when the instrument is in the HOLD mode. DET ZERO is adjusted for a flashing + or - sign with a short on the input and the range set to 10 volts.

CIRCUIT DESCRIPTION
A5, A-D CONTROL LOGIC
SCHEMATIC #7-03762301

The A5 board in the Model 7110A carries the clock oscillator and the logic gates which are involved in the analog-to-digital conversion. A5Q6, in conjunction with A5VR1 and A5R16, provides a 5 volt supply voltage above the -20 volt supply for these logic elements. Inputs to this board include: the signal from the comparator on terminal 18&V, the Full Scale pulse on terminal J&8, the Complement pulse on terminal F, and the starting signal on terminal 4. Outputs from this board are: gated clock pulses on terminal 3, negative polarity pulse on terminal E, $\overline{\int}$ on terminal 10, $\overline{\int E_x}$ on terminal 12&N, $\int E_x$ on terminal 11&M, $\int +E_r$ on terminal 1&A, and $\int -E_r$ on terminal 2&B. The voltage on the terminal from the zero detector ranges from -.5 to ±3 volts and it is shifted by the action of A5Q5 to the range of -20 to -17. The zero detector signal at the collector of A5Q5 is inverted and amplified by A5Q4 and then by A5Q3 which are capable of sinking the currents from the gates A5U4C and A5U4D.

A5Q2 and associated components comprise the crystal oscillator which operates at 6 MHz in the standard configuration or at 5 MHz in the 50 Hz option. A5Q1 is a buffer to secure logic gate driving capability. The clock signal out of the buffer is inverted by gate element A5U1D and applied to one input of gate A5U1C. The other input of A5U1C is connected to the digital count and control board through a pulse transformer which has a rectangular wave out when the digital section is ready to start a new measurement. When the clock and the start signals are both high, the flip-flop, consisting of A5U1B and A5U3A, will be set and, in turn, will gate on the clock and make $\overline{\int}$ on terminal 10 high.

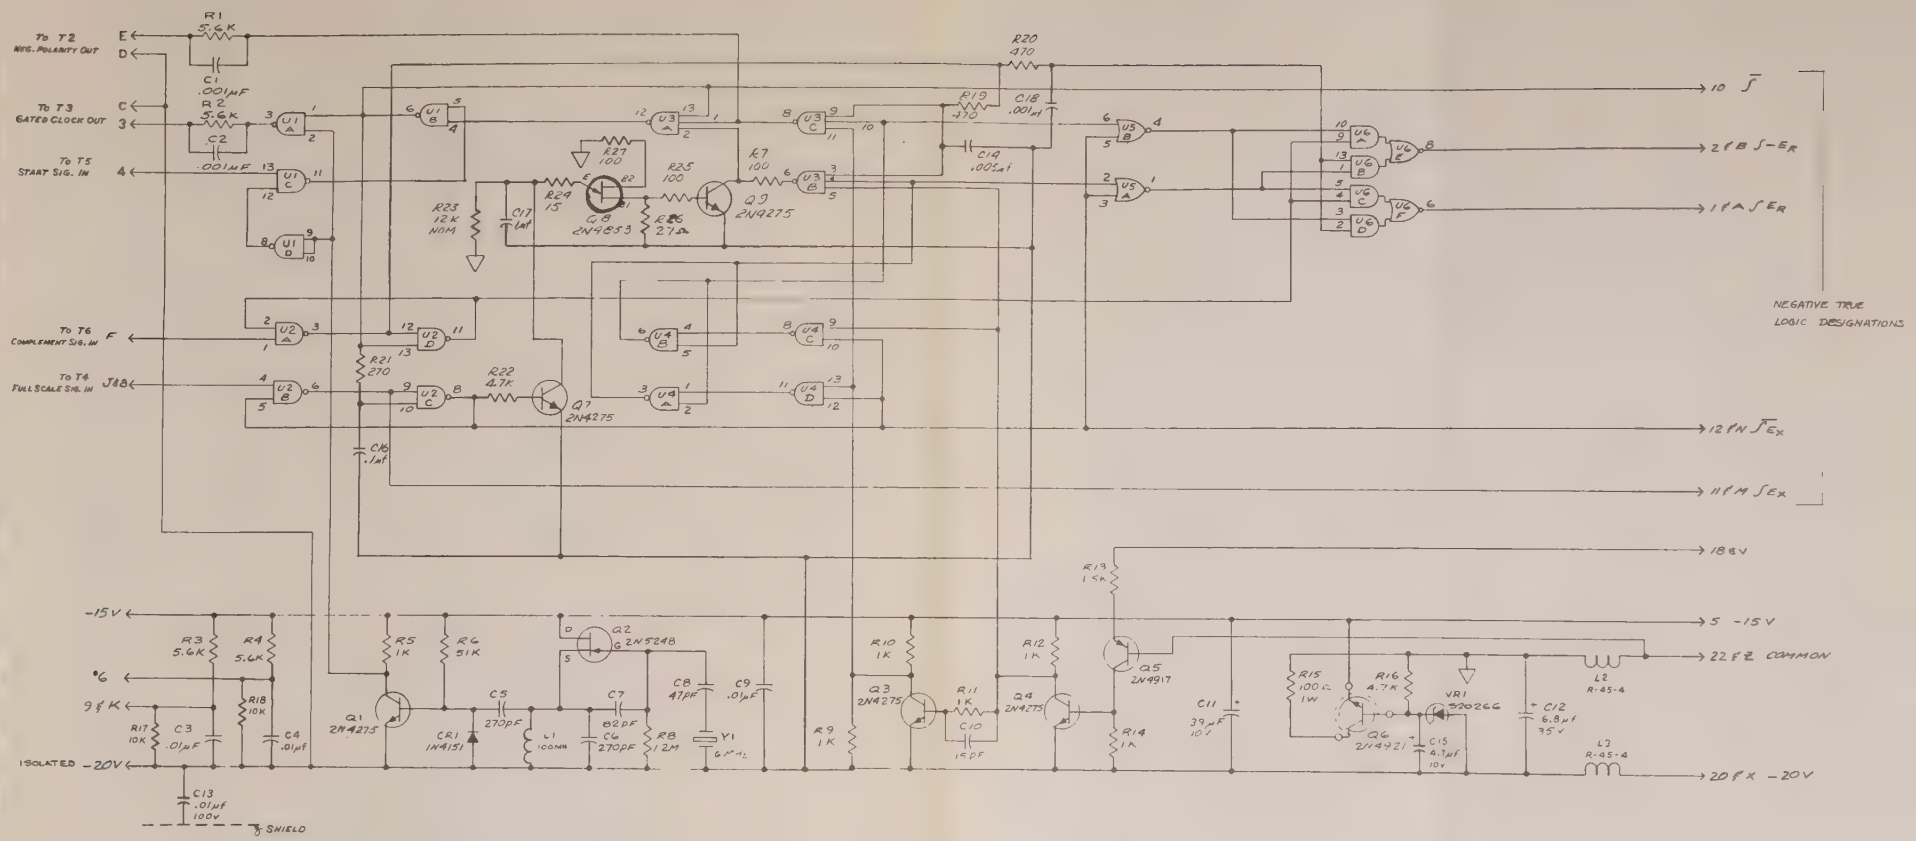
Integration of the unknown voltage now proceeds until 10^5 counts are accumulated and the Full Scale pulse sets the Full Scale flip-flop consisting of A5U2B and A5U2C. During this period the polarity flip-flop, consisting of A5U4A and A5U4B, has assumed the same state as the output of the zero detector at the end of the $\int E_x$ period. If the input voltage is negative, the output of the zero detector is negative; the collector of A5Q4 is high and that of A5Q3 low; gate A5U4C has both inputs high; polarity flip-flop has A5U4B output high which primes one input of gate A5U3C and the low output of the polarity flip-flop; and the low state on terminal 8 of A5U2C, Full Scale flip-flop, makes 11 of A5U5A high. With 11 of A5U2D, complement flip-flop, high, the output of A5U6C will be high and 6 of A5U6F will be low, thus, connecting the positive reference to the integrator and causing the output of the integrator to become more negative.

After an additional 100 clock pulses, the Complement pulse is generated in the digital count and control circuits and coupled into the A-D Control Logic via the pulse transformer. This pulse

sets the complement flip-flop, which after 3 μs delay, primes both gates A5U3B and A5U3C, which turns gate A5U6C off and A5U6B on, thus disconnecting the positive reference and connecting the negative reference voltage. The negative reference voltage now causes the output of the integrator to become more positive and approach zero volts.

When the output of the integrator goes through zero volts, the collector of A5Q3 will go high, making the three inputs of gate Q5U3C high and its output low. The integrate flip-flop will be reset, gating off the clock and resetting the Full Scale flip-flop after a 20 μs delay, the complement flip-flop, and changing the $\overline{J}$ output to its true condition. The negative-going transient at terminal 8 of A5U3C is also coupled through a transformer to the digital count and control circuits to set the negative polarity flip-flop so that the negative sign can be energized. The case for positive input voltages is similar except that no polarity pulse is generated.

Because false on-scale readings can be indicated if a low voltage is used as the reference input and a voltage greater than twice the reference input is applied to the unknown input terminals, circuitry is incorporated to generate a false zero detection when the integration of reference time exceeds about 22 ms, or 1.3 times full scale. When the full scale flip-flop is set, A5Q7 is turned off and A5C17 is charged through A5R23 until the trigger voltage of A5Q8 is reached and a pulse is generated across A5R26. This pulse turns A5Q9 on for a short time to make terminal 2 of A5U3A low. This is equivalent to a zero detection signal and causes the logic circuitry to continue its cycle as if zero detection had been reached. The reading will be in the range between 130000 and 195000 and the off-scale light and signal output line will be energized. This circuitry allows the digital portion of the instrument to recycle when the Integrator Zero Detector board is removed from the equipment and can be an aid in servicing the digital portion of the apparatus.



NOTE

1. UNLESS SPECIFIED, RESISTORS ARE ±5%, 1/4 W.
2. U1, U2 & U4 ARE SN7400N
   U3 IS SN7410N
   U5 IS SN7402N
   U6 IS SN7451N
   ALL I.C.s: PIN 7 TO -20V
   PIN 14 TO -15V
3. SELECT R_X (R23) TO OBTAIN A DISPLAY BETWEEN 190000 & 190000 WITH >100% OVER RANGE INPUT LEVEL.

CIRCUIT DESCRIPTION
A6, REFERENCE AND POWER SUPPLY
SCHEMATIC #7-03755101

The A6 board in the guarded section contains the regulator section for the main power supply, input buffer amplifiers for the external reference, and the internal reference supply. A6U6 is a μA 723 type of monolithic integrated circuit in the typical positive regulator configuration set to drive the pass transistor mounted on the rear wall of the guard. Shorts are provided across A6R28 and A6R29 which can be removed to increase the output voltage of the supply. Removing the short across A6R29 raises the voltage about 2.9%, from across A6R28 raises the voltage by 5.8%, and from across both resistors raises the voltage by 8.4%. The adjustment which comes closest to 20 volts is the desired adjustment, and about 1.5% deviation is tolerable.

The negative supply regulator employs A6U7 (μA 723) in the negative regulator configuration with Q1 on the rear guard wall as the pass transistor for the load current. Shorts around A6R33 and A6R34 can be removed to give a 3%, 6.4%, or 9.4% increase in the output voltage, and the negative output should be adjusted to within about 2% of -20 volts.

The internal reference supply for the 7110A on this board involves A6VR1 and A6U4 along with associated resistors. A6VR1 is a 6.2 volt Zener diode which has been selected for low-temperature coefficient and for low-voltage drift with time. A6U4 is a high-gain operational amplifier in a gain-adjustable circuit adjusted to amplify the voltage across A6VR1 by about 1.6 to give an output of 10 volts. Since the output is at a well-regulated voltage, the resistance network supplying the bias current in A6VR1 is connected to this point to achieve a relatively constant bias current to the diode. A6R11 allows for a small adjustment in the magnitude of the bias current and can be set to a value which will result in a very-low temperature coefficient for the total supply. Shorts around resistors in the string A6R15 through A6R20 are installed to give close to 10 volts as possible with A6R14 at mid-position.

A6U1, U2, and U3 are connected in a gain-of-1 configuration with means for adjusting the dc common mode signal rejection to a high value, with means for adjusting the gain around 1, with means (A6R9) for adjusting the zero input offset, and with a very high input impedance so that reference voltage sources will not be loaded significantly if their internal impedances are low. The differential input impedance is about 2 MΩ and the line to signal common impedance is 1 MΩ. A6U1 and A6U2 are connected as unity gain voltage followers and then by resistance attenuator networks to A6U3. The GAIN and CMR adjustments are made by a series of steps during calibration.

A6U5 and associated resistors function as the inverter of either the internal or external signal. A6R25 is adjusted to reduce the offset of A6U5 to zero. The two RATIO ZERO adjustments are more critical for the lower values of external reference voltage. The -REF adjustment is made to set the inverter gain at the time the -10 volt sensitivity is being checked.

CIRCUIT DESCRIPTION
A10, ANALOG MOTHER-BOARD ASSEMBLY
SCHEMATIC #037204-7-1

The A10 Analog Mother-Board Assembly, carries sockets and interconnections for the analog boards, power supply components, and some of the circuit elements required in the control functions.

The main plus and minus 20 volt supply employs rectifiers A10CR1, 2, 3, and 4, and filter capacitors A10C1 and A10C2. The regulator circuits are on the A6 board, Reference and Power Supply.

The negative high-voltage bias supply for the Ohms Current Source high-voltage protection circuit is comprised of rectifiers, A10CR16, 17, 18, and 19, filter capacitor A10C13 and bleeder resistor A10R25. The capacitors,A10C14A and A10C14B, tend to filter out rectifier noise.

The rectifiers and filter capacitor elements for the floating power supplies for the Input amplifier are A10CR5, 6, 7, and 8, and A10C3 and A10C4. This circuit is mounted on a small board enclosed in a shield which is connected to the second shield, SH 5.5, on the power transformer. This shield is driven by the amplifier whose input is terminal 8 and 40. This amplifier input has negligible loading on the range resistor between the low side of the input amplifier and signal common. The unity gain amplifier output through A10R22 drives the capacitance between the shields of the power transformer and other leakage paths, which otherwise might shunt the range resistor.

Plus and minus 18-volt regulated supplies for the Ohms Current Source, are generated by the components connected between board terminals 4, 5, and 6 and A10A7, A10A8, and A10A9 terminals 1C, 2B and 3C. This regulator is similar to the one on the A6 board. It is isolated from the main power supply so that an isolated current source can be constructed for the four-wire ohm-measuring current source. A10Q13 drives a solenoid which couples information across the GUARD to indicate whether or not an option board is installed when the option's function is called. A10CR20 is grounded when kΩ is called and A10CR21 is grounded when AC is called; and when ungrounded, these points have an open circuit voltage of about 20 volts. If the AC converter board is installed, the junction of A10R15 and A10CR22 is grounded so that there will be no forward base bias on A10Q13 and no current will flow in the solenoid if AC VOLTS is called by the function switches. If the board had not been installed, then the junction of A10R15 and A10CR22 would not be grounded, and A10Q13 would have forward base biasing which will cause current to flow in the solenoid. The magnetic field coupled across the guard will operate the reed switch and generate the BAD RANGE logic signal which, in turn, will light the * on the readout panel. Operation for KΩ is similar except that the other pair of diodes are involved.

CIRCUIT DESCRIPTION:

Option 10, A9, AC Converter changes an ac voltage to a dc voltage proportional to the rms value of the ac voltage. To accomplish the conversion, the A9, AC Converter P.C. board utilizes a switch selectable input attenuator, an input operational amplifier, and a true rms converter module.

When AC is selected, the HI input connector of the instrument is connected to the input of the AC Converter board on pin 15 & S. For the 10 V, 100 V, or 1000 V ranges, control signals turn on relays and close switches A9S1, A9S2, or A9S3 through a magnetic field generated by A9L1, A9L2, or A9L3. A9CR3, A9CR4, and A9CR5 are used to bleed the collapsing coil fields. All switches are open for the 1 V range. When one of these switches is closed, A9R9, in series with A9R1 as a ÷ 2 network, is shunted by a resistor-capacitor combination which increases the attenuation of the input by a factor of 10, 100, or 1000 for a total of 20, 200, or 2000 attenuation factor. No switches are needed for the X1 attenuation position or a factor-of-2 total attenuation. Overload protection is provided by diodes A9CR1 and A9CR2.

A9U1 is a gain-of-2 operational amplifier with a high-input impedance providing light loading on the input attenuator and a low output impedance for driving the following ac converter stage.

A9U2 is an rms ac-to-dc voltage converter module. The output dc voltage Vo at pin 5 & E for an input voltage Vi to the module A9U2 on pin 25 is given by the following relationship:

$$Vo = \left[1/p \int_o^p (Vi(t))^2 \, dt \right]^{1/2}, \text{ where } p = \text{period}$$

t = pulse width time.

CIRCUIT DESCRIPTION
A11, DIGITAL COUNT AND CONTROL ASSEMBLY
SCHEMATIC #037208-7-1

The A11 Digital Count and Control Board, carries the circuits for counting the gated clock pulses, controlling part of the operational cycle of the measurement, and storing and presenting the measured value.

A11U12, 13, 14, 15, and 16 are decade counter elements. A11U17 is a dual JK flip-flop unit, half of which is connected to act as a complementing flip-flop at the end of the counting chain, with the domain of numbers ranging from 000,000 to 199,999. The count chain is driven by pulses coupled by transformer across the guard and amplified by A11Q18. The count chain is broken between the first flip-flop in the 10^2's order and its following scale of 5, with a gate and an inverter, A11U19, inserted. A11U6, 7, 8, 9, 10, and half of A11U17 are latches for storing the previous measurement number while the succeeding measurement is being made. A11U1, 2, 3, 4, and 5 are decoder-drivers for the gas discharge indicators. A11U11 is a dual JK flip-flop, one section of which is set by the negative polarity pulse and the other section of which functions as the latch, with A11Q13 and A11Q14 the drivers for the gas discharge (+,-) display tube. A11Q1, 2, 3, 4, 5, 15, 17, and 32 are annunciator driver transistors.

When clock signals are being supplied to the circuit, a .6 MHz signal exists at terminal 11 of A11U12. This signal is rectified by A11CR8 and A11CR9, charging A11C13. This signal is buffered by A11Q25 and applied to the trigger circuit comprised of A11Q26 and A11Q27 and associated components. The collector of A11Q27 takes on two values, being high when the unit is counting and low when it is not counting. This signal is inverted by A11U23. When counting stops in response to a zero detection in the analog section, terminal 6 of A11U23 goes high and the one-shot, A11U23C and A11U23D, is triggered to generate a pulse about 5 µs wide, which is named Transfer. When terminal 8 of A11U23 goes negative for the pulse duration, A11Q23 is turned off and the transfer line to all the latches goes positive. This line going low causes the highest order digit and the polarity sign information to appear at the output of the latch elements of the respective flip-flops.

The negative-going signal on the TRANSFER line triggers a one-shot, A11U22D and A11U25C, which generates a pulse named AUTO STROBE of about 5 µs duration. This pulse is inverted and delayed by A11U25F, followed by A11L31 and A11C32, and applied to gates A11U32A and A11J32C. Action of this circuit will be discussed in a later section. A11U24A, terminal 6, will go low turning A11Q28 off and allowing the emitter of the UJT, A11Q31, to rise at a rate determined by A11C30, A11R76, and the variable resistance of the front panel SAMPLE RATE control. The positive pulse generated on triggering of A11Q31 across A11R57 turns A11Q23 on and the negative pulse at its collector triggers the one-shot, A11U24B and

A11U25D, generating the negative reset pulse at 8 on A11U25D. The negative pulse is used to reset A11U26 to the BUSY condition, to reset half of A11U17 to the 1 condition, and half of A11U11 to the plus polarity condition. A11Q24 inverts the reset pulse for the counter elements and for the flip-flop, A11U20B and A11U20C, which, when reset, enables the multivibrator, A11U20A and A11U20D, whose output is in turn coupled across the instrument GUARD to start the measurement cycle.

The A-D Logic Control board now takes over control of the measurement cycle. When counting starts again, the input on terminal 4 of A11U20B goes negative, resetting the flip-flop and turning the multivibrator off. After 100,000 counts have been accumulated, a one-shot, A11U19A and A11U19D, is triggered by the 1 to 0 transition at terminal 13 of A11U17. The output of this one-shot generates the Full Scale pulse that is coupled across the GUARD to the analog section, and it resets both sections of A11U18, making terminals 9 and 12 low. With terminal 12 low, the gate between the scale of 2 and the scale of 5 sections in the 10^2 counter is opened. The carry pulse from the 10's counter occurring at the 99 to 00 transition sets one of the flip-flops making terminal 8 low and terminal 9 high. Terminal 8 going low turns off A11Q19 to generate the complement pulse which is coupled across the GUARD. Terminal 9 going positive primes the other flip-flop so that the next carry pulse will cause it to be set, which closes the gate between the two sections of the 10^2 counter with a zero in the first section. Counting continues in the normal pattern until the clock signal is gated off in the analog section. In the event that the clock is gated off before 200 counts have been generated after Full Scale, terminal 12 of A11U18 will be low and A11Q21 biased off. The TRANSFER pulse will turn A11Q22 off, opening the emitter circuit of A11Q24 which resets the count chain to zero, and gives a count of zero for all conditions which might cause the clock to be gated off before the 200th pulse is generated. This circuitry functions to give good linear response for voltage in the neighborhood of zero.

The autoranging function is accomplished by using the data stored in the latches to operate gates to either change down-range to a more sensitive condition, make no range change, or to up-range to a less sensitive range. The same gates are also used to generate the signal which energized the annunciator which shows overrange. Output at terminal 6 of A11U28 is low if the count is less than 11×10^3.

If this voltage is low and if the control voltage AUTO is also low, then terminal 9 of A11U34 will be high. If the instrument is not on the lowest range, terminal 10 high, then during the AUTO STROBE pulse on terminal 11, a negative pulse as wide as the AUTO STROBE pulse will be generated at the down input terminal of the forward-backward counter, A11U35, and its state will change to a lower number. Outputs from the first three stages of this counter are coupled into a decoder-driver, 3 bits, 1, 2, and 4, and the 8th bit input to the decoder is connected to the AUTO

control which is high when not in the autorange condition, thus, adding the 8th bit to the count from the counter. With the 8th bit high none of the decoded outputs 0 through 7 will be low, but if AUTO is low then the three input states will be decoded and one of the range control lines will be low. The 4 and 5 count out of the decoder are tied together so that in the 100-volt range two trials are made and the unit has more time to come to a correct reading following the step change of input due to range switching. The 100-volt range has the slowest response time because of the high source impedance of the input attenuator. The 0 and 1 count are tied together to use the eight states of the decoder output.

Up-ranging functions in a similar manner with terminal 6 of A11U30 low on counts of 3 and 7 x 10^4, and terminal 6 of A11U32 high on counts of 3 through 9 x 10^4. Terminal 11 of A11U30 is low for counts 13 through 19 x 10^4 making terminal 1 of A11U33 high if AUTO is low. This signal is added with HIGHEST range signal and the AUTO STROBE pulse to give a negative pulse for up ranging. When a range change is indicated, a signal is generated at terminal 8 of A11U29 and fed to terminals 4 and 5 of A11U27. The other input to this gate is driven by the delayed AUTO STROBE pulse and if a range change was indicated, then flip-flop, A11U28B and A11U29D, is set. This action turns off the normal sample rate delay circuit and turns on the 40 ms delay generator whose pulse output drives the reset circuit to make a second reading, and also to reset this flip-flop. This circuit causes the unit to make one more reading on the supposedly correct range selected by autoranging. This results in a more accurate reading since the settling time of the unit to a step change is not appreciably shorter than the 40 ms delay between a range change and the next reading when the filter is being used.

The output from the above flip-flop is also coupled to one of the gate inputs of the JK flip-flop A11U26 which is reset by the reset pulse and set by the differentiated COUNTING control signal. A PRINT signal is generated when no range change is required on AUTO RANGE or when the start signal has been stored.

A flip-flop using two sections of A11U22 can be set by the front panel pushbutton or by grounding terminal 46 to the BCD output connector, J207. When this flip-flop is set, the COUNTING logic level will trigger the multivibrator, A11U21, whose period is greater than the sum of the transfer pulse and the AUTO STROBE pulse, and the trailing edge of this pulse, resets the start flip-flop and it in turn drives the reset generator. This circuitry allows one to instruct the instrument to make a measurement and it will then make a complete new reading by the most expeditious manner. The instrument cannot be interrupted in the middle of its integration cycle so that if it is in mid-cycle, the operation continues until the clock is gated off.

For those applications where the data receiving device cannot store the information out immediately, two methods are provided for the data receiver to halt the cycle. One is the INHIBIT

RESET and the other is the INHIBIT TRANSFER command connection. If the INHIBIT RESET line is grounded after the PRINT command comes high, then the cycle stops. The cycle continues with a delay to reset and the next measurement with the release of the INHIBIT RESET line. If the INHIBIT RESET line is grounded and the instrument is given a START command, it will make a measurement and wait for the next START command before continuing. If the data receiver needs to hold previous data after it has generated a START command, then the data receiver can ground the INHIBIT TRANSFER line and hold the transfer of new data until after the release of this line. Hold TRANSFER should not be generated until after BUSY is received. For fastest data transfer: receive PRINT, generate START, receive BUSY, generate HOLD TRANSFER, extract data, and release HOLD TRANSFER.

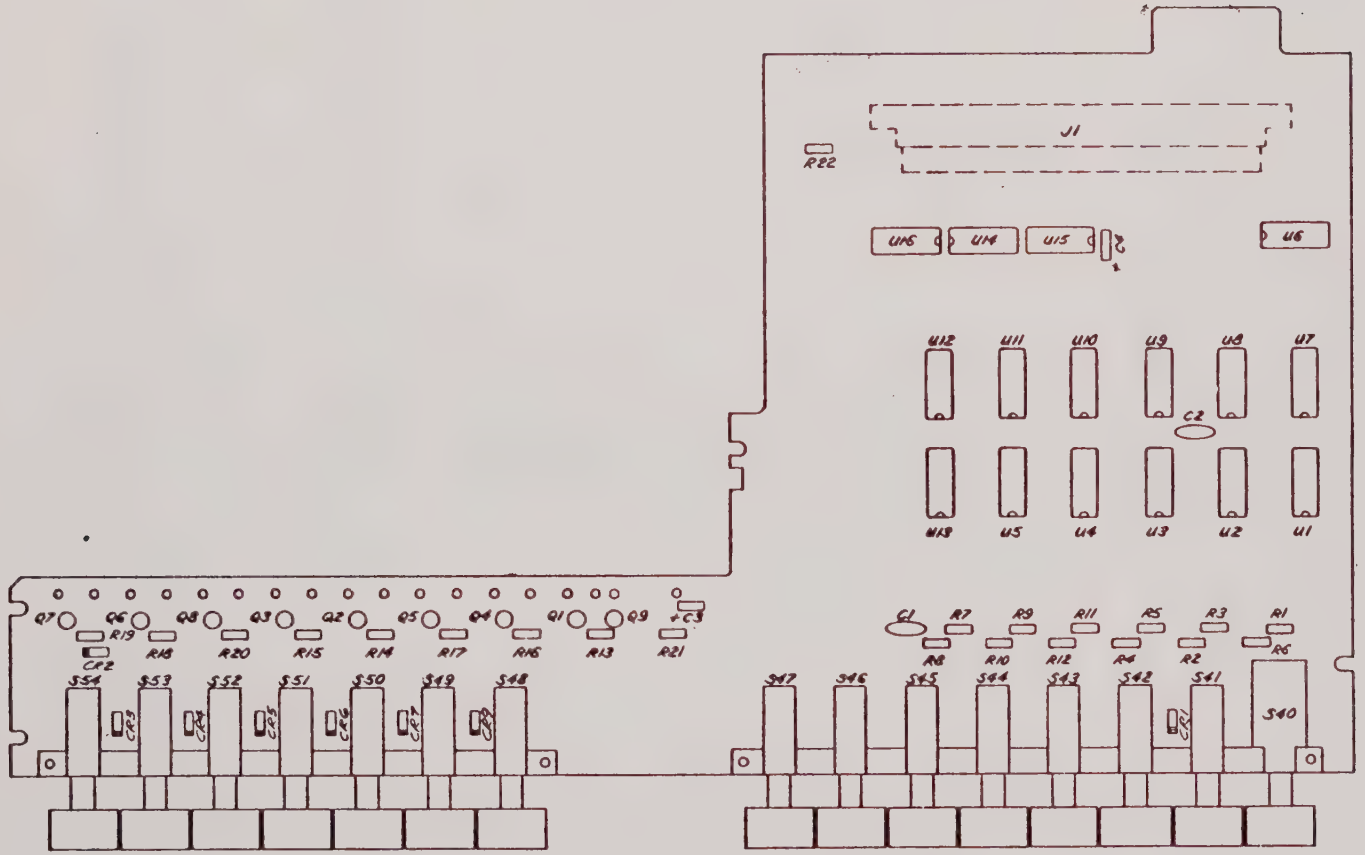
CIRCUIT DESCRIPTION
A12, SWITCH
SCHEMATIC #037212-7-1

The A12 Switch board, provides logic circuits for manually and remotely selecting the proper FUNCTION and RANGE. The front-panel-selected operating modes are switched by control lines A12J1 from either front panel pushbutton switch closure for pin grounding on remote connector A12J2. Both the digital and analog circuitry are set-up with this Switch board. Control lines from the A12J1 connector activate the A11 Digital Count and Control circuitry in the digital section and lines from A12Q1 through A12Q9 activate A1, Guarded Control circuitry in the analog section.

To select a FUNCTION, one or more of the Front panel FUNCTION pushbutton switches, A12S48 through A12S54, is depressed. Similarly, RANGE selection involves depressing one of the front panel RANGE pushbutton switches, A12S40 through A12S47. To explain the Switch board, one RANGE & FUNCTION Switch selection will be used. For instance, selecting the .1 RANGE and the VDC FUNCTION closes switches A12S48 and A12S42 respectively. The A12S48 switch closure places a low on the following pins: 12 of A12J1, J of A12J2, 6 of A12U1, 2 of A12U3, 8 of A12U4, and 8 of A12U14. Also, the A12S42 switch closure places a low on the following pins: 5 of A12U1, 3 of A12U1, 9 of A12U1, and 5 of A12U2. With these pins low, a number of elements change state: The lows on pins 5 and 6 of A12U1 place a high on pin 4 of A12U1. The high is inverted by A12U6 with a resultant low on pin 10 of A12U6. Pin 21 of A12J1 is now low which makes pin 21 of A11J1 also low. With a low on its base, A11Q5 is turned on lighting the incandescent lamp A11DS4, mVDC. The high on pin 4 of A12U1 is also inverted by A12U7 which places a low on pin 15 of A12J1. Pin 15 of A11J1 is now low, turning transistor, A11Q7, on and lighting the decimal point of readout tube A11V3.

A low also appears on pin 9 of A12U14 for the following reasons: The BAD RANGE is high so pin 10 of A12U16 is low which places a low on pin 11 of A12U16. The TEST line is low so pin 12 of A12U16 is low; thus, pin 13 of A12U16 is high, making pin 4 of A12U13 and pin 9 of A12U14 low.

With pin 8 and 9 of A12U14 now low, pin 10 goes high, turning on transistor A12Q1 which activates coil L4. L4 closes reed switch A1S4 on the A1, Guard board. This grounds pin 18 of A1 and pin 9&W of A3. Thus, coil A3L19 is activated, closing switch A3S19, which selects the proper negative feedback resistance value for the A3A1 Input Operational amplifier.



A12, SWITCH ASSEMBLY #037212-4-1 REV B

CHAPTER 6
OPTIONS AND ACCESSORIES

6.1 INTRODUCTION

This chapter contains descriptions of the standard options and accessories available for the Model 7110A DMM. Special options will be included at the end of this chapter when applicable.

6.2 STANDARD OPTIONS

Each option, with a few exceptions, contains a description, assembly, schematic, and a parts list:

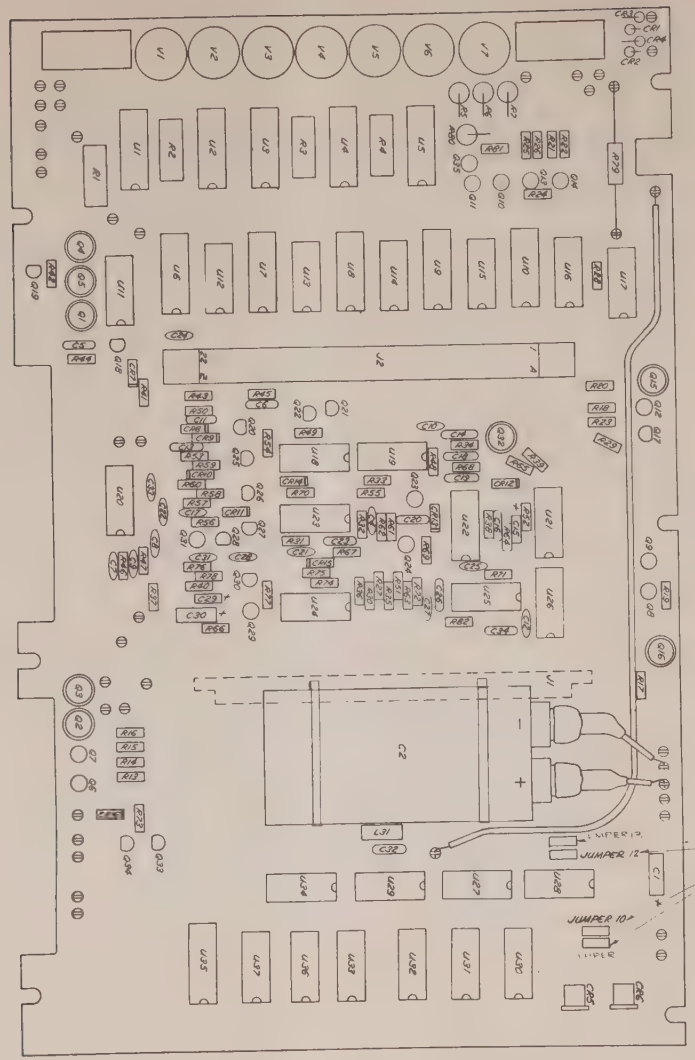
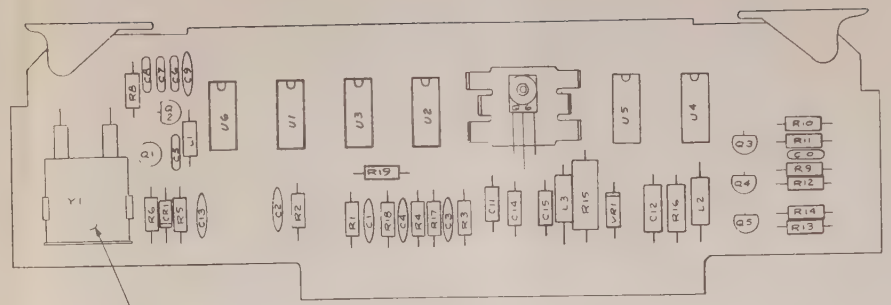
CIRCUIT DESCRIPTION
OPTION 01, 50 Hz LINE OPERATION
FINAL ASSEMBLY #037234-4-1

With Option 01 installed, the Model 7110A DMM will operate on 50 Hz line input. The modification includes substituting a 5 MHz crystal for the 6 MHz crystal, Y1, on the A5 Analog to Digital Control Logic P.C. board; and removing jumpers 10 and 12 and installing jumpers 11 and 13 on the A11, Digital Count and Control P.C. board.



DIGITAL MOTHER PC ASSY
A11



A/D PC ASSY A5

NOTES:
1/ REMOVE TOP COVER FROM UNIT IF INSTALLED
2/ MODIFY A5 & A11 AS SHOWN
3/ REPLACE TOP COVER
4/ CHANGE UNIT REAR PANEL LABEL TO 01 OPT 50Hz

OPTION 01, 50 Hz LINE OPERATION
ASSEMBLY #037234-4-1 REV A

CIRCUIT DESCRIPTION
OPTION 02, A9, AC CONVERTER
SCHEMATIC #037196-7-1

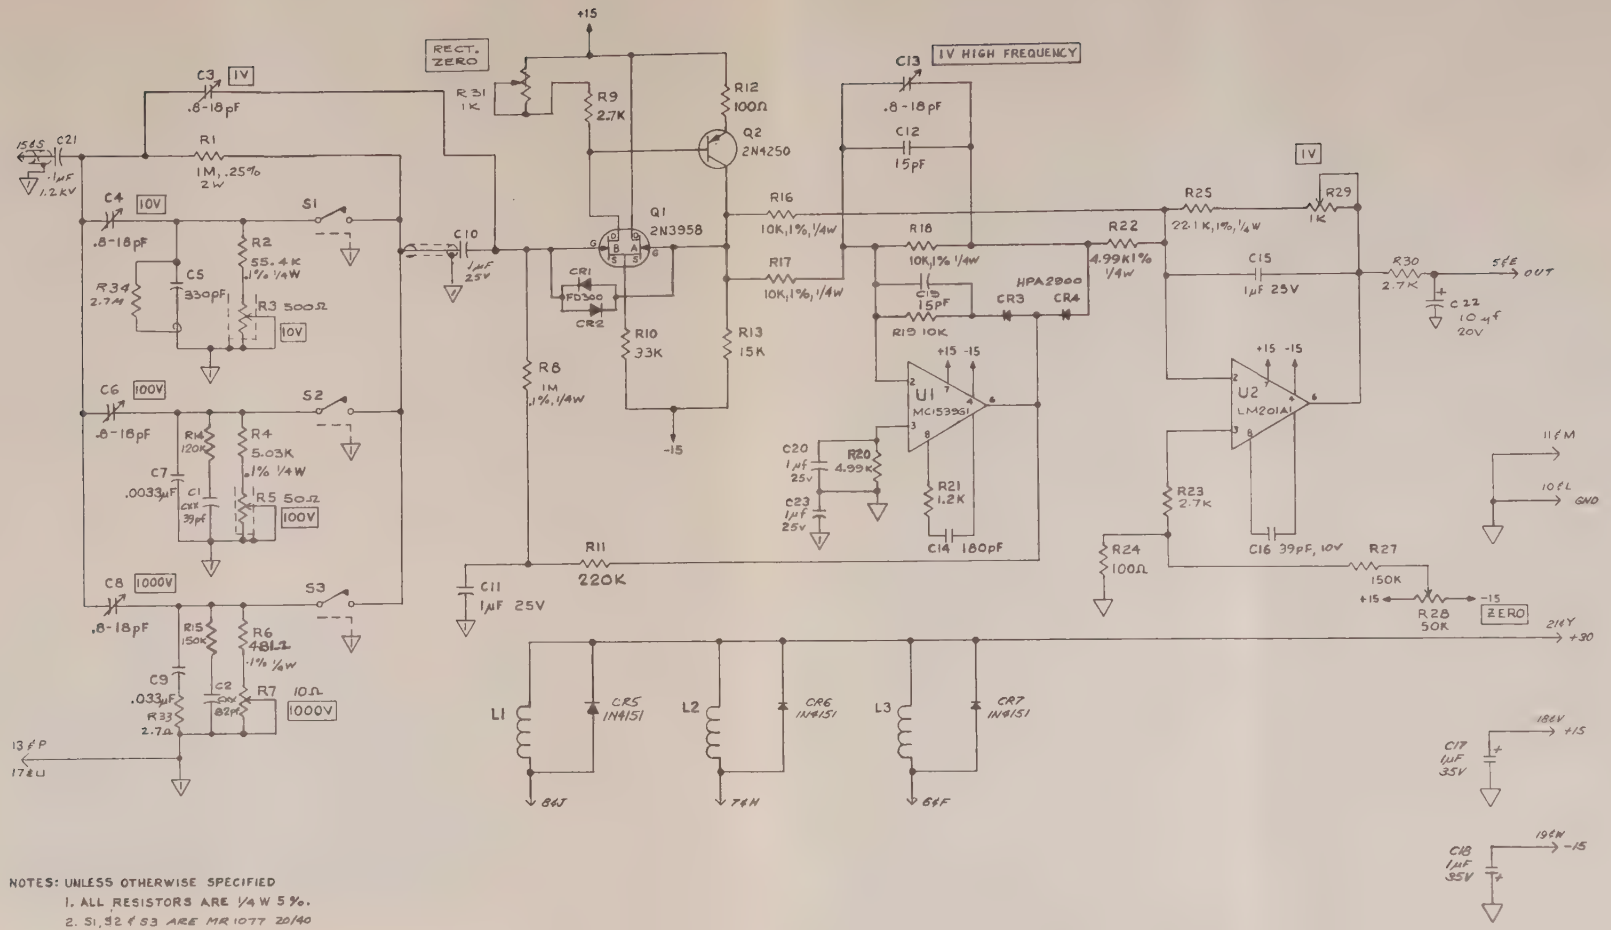
The A9 AC Converter board changes ac voltage to a proportional dc voltage. The resulting dc voltage is then measured by the multimeter. To accomplish the conversion, the AC Converter board contains an attenuator circuit and an ac-to-dc conversion circuit.

When ac is selected, the HI input connector of the instrument is connected to the input of the AC Converter. For the 10 V, 100 V, or 1000 V ranges, range control signals through diodes A9CR5, A9CR6, or A9CR7 turn on relays and close switches A9S1, A9S2, or A9S3 through a magnetic field generated by A9L1, A9L2, or A9L3. When one of these switches is closed, A9R8 and its associated shunt capacitance is shunted by a resistor-capacitor combination which increases the attenuation in the input by a factor of 10, 100, or 1000. A small variable capacitor is also added in shunt with A9R1 and A9C3 to adjust the high frequency attenuation to obtain a flat frequency response. Elements A9R33, A9R14, A9C1, A9R34, A9R15, and A9C2 are employed to compensate for the variables in the other elements of the attenuator.

A9Q1 and A9Q2 comprise a unity gain amplifier with a high input impedance, a very-light loading on the input attenuator, and a low-output impedance for driving the following stages.

Amplifier A9U2 has negative feedback provided by A9R25, A9R29, and A9C15 with input currents through A9R16 and A9R22. The current through A9R16 is directly proportional to the input voltage. Amplifier A9U1 inverts the input signal and generates negative half-wave rectified signals at the junction of A9CR4 and A9R22. The negative half-wave rectified signal results in a current through A9R22 to the input summing junction of A9U2 which is twice the value of current through A9R16 and opposite in sign. As a result, only negative half-waves of current are effectively fed to A9U2 which amplifies the dc component and filters out much of the ac components through the action of A9C15. The negative dc output voltage is proportional to the full-wave average value of the input voltage and the value of A9R25 and A9R29 is adjusted so that the reading of the DMM is equal to the RMS value of a sine wave.

OPTION 02, A9, AC CONVERTER ASSEMBLY #037196-4-1 REV C



NOTES: UNLESS OTHERWISE SPECIFIED
1. ALL RESISTORS ARE 1/4 W 5%.
2. S1, S2 & S3 ARE MR1077 20/40
3. L1, L2 & L3 ARE UM24P

CIRCUIT DESCRIPTION
OPTION 03, A7, OHMS CURRENT SOURCE
SCHEMATIC #037192-7-1

The A7 circuit board in the analog section of the Model 7110A DMM functions as an isolated current source to establish predetermined currents in unknown resistors so that the voltage measuring portion of the instrument can make a determination of the potential drop in any part of the external circuit specified by the operator. The reference currents are derived from an A7A1, RVL-3 voltage reference unit at about 10 volts and series dropping resistors to the summing junction of an operational amplifier. For the .1, 1, and 10 Ranges, the current is 1 mA derived from the 10 volt drop in a 10 kΩ resistor. For the 100 Range, the current is .1 mA derived from the 10 volts drop in 100 kΩ. On the 10,000 Range the reference voltage is attenuated so that, effectively, there is a 1 volt drop in a 1 MΩ resistor to give a 1 μA of current.

Since the input current of the operational amplifier is much smaller than these reference currents, and since the input voltage will be very small, then the same current will flow in the external resistance path as into the summing junction from the reference source. The voltage developed across the elements in the external path must be less than 15 volts in order for the current source to remain in its linear operating region.

Protective circuits are incorporated around this amplifier to prevent failure in the event that a high voltage source should be connected to the current source. If the output, 20&X, is positive with respect to 22&Z, then A7CR4 will be reverse-biased with most of the external applied voltage. If the polarity is reversed then the external voltage will be added to the -265 volt bias supply to drive current through the 200 kΩ resistor and back-bias A7CR3. Potentials across the amplifier will remain within rated limits under the adverse condition of inadvertant application of voltage to the current source. Resistor network A7A3 provides for the coarse adjustment of the output of A7A1, RVL-3, in the process of making the instrument calibration. Resistors in this assembly are shorted to obtain the one of sixty-four series resistor values which will bring the fine control into the required voltage range.

The shield connections 19&W and 21&Y, are connected to the power supply common of the current source, and are carried to the rear of the front panel and to the outer terminal of the triaxial connector used on the rear of the instrument. In making connections to the rear of the unit, two coaxial cables should be used with the center conductors connected to the current source and the two shields connected to the current source shield. These cables can then be carried for considerable distance without a leakage path between the central conductors so that remote high resistances can be measured with accuracy. Care needs to be exercised in

using the front panel to ensure that there are no current paths between the current source terminals, other than the resistor under test, or a low reading will result.

		Max. Size
R4	900,000 Ω	0.875L X 0.328D
R5	111,250 Ω	0.656L X 0.250D
R7	900,000 Ω	0.875L X 0.328D
R9	90,000 Ω	0.656L X 0.250D
R11	10,000 Ω	0.656L X 0.250D

TC of each resistor to be less than 5 ppm/C over the range from 0 to 70 C. Maximum voltage drop in any resistor in the set in the application is 10 volts dc.

Resistors are matched so that the sum of resistance values, $R_4 + R_5 + R_7 + R_9 + R_{11} = 2{,}011{,}250\ \Omega \pm 0.5\%$. The following ratios and tolerance-on-ratio are held.

$R_4 = R_7$

$$\frac{R_4}{\Sigma R} = \frac{900{,}000}{2{,}011{,}250} = 0.447482 \quad \pm 0.05\%$$

$$\frac{R_5}{\Sigma R} = \frac{111{,}250}{2{,}011{,}250} = 0.0553138 \pm 0.05\%$$

$$\frac{R_9}{\Sigma R} = \frac{90{,}000}{2{,}011{,}250} = 0.0447482 \pm 0.05\%$$

$$\frac{R_{11}}{\Sigma R} = \frac{10{,}000}{2{,}011{,}250} = 0.0049720 \pm 0.05\%$$

CIRCUIT DESCRIPTION
OPTION 05, A14, CONNECTOR BCD (8-4-2-1)
FINAL ASSEMBLY #037221-4-1

The A14 BCD Connector, Option 05, is a buffer amplifier and signal conditioner which transmits data to a remote receiver. Signals from A11, Digital Count and Control, are routed through A14, BCD Connector, to J207. All BCD, decimal point, function, and control information is available to the remote equipment. Ground true BCD inputs are routed through inverters A14U1, U2, U3, and U7, and converted to positive true signals. Decimal point information is applied through NAND gates, A14U4, and furnished to the receiver as the negative exponent of the measurement, N X 10^{a}. Where (N) is the number measured and (a) is the negative exponent.

Function signals are applied, at ground true level, to NAND gates A14U5 and U6. The positive true BCD output is coded to designate the function. See BCD pin assignments (05 Option) Table 3.5, page 3-11. Polarity information is furnished through two inverters connected in tandem. If the signal at pin 2 of J2 is low, pin 6 of A14U1 is positive and the polarity signal at pin 42, J207, is a positive true, indication of + polarity. A high input at pin 2 will result in a positive true indication of - polarity at terminal 17 of J207. Overload is indicated in a like manner but uses only a single inverter. A low input results in a positive true $\overline{\text{OL}}$ output through inverter A14U1. A high input is routed directly to pin 43 of J207, indicating an overload, 1.3 times full scale, condition.

Positive 5 V is furnished to the inverters and gates from J2, pin R, and 0 V from J2, pin F. A voltage divider network, A14C1, R3, R2 and R1, provide outputs of 0.5 V at pin 24 and 2.5 V at pin 25 of J207. This voltage is available as a reference voltage for comparison by properly equipped remote receivers. Control information signals, both to and from the DMM, are ground true signals, routed directly through the board. $\overline{\text{INHIBIT RESET}}$, $\overline{\text{START}}$ and $\overline{\text{INHIBIT TRANSFER}}$ (positive true labels) are received from the remote equipment. PRINT and BUSY are originated in the DMM. The open START signal is 5 V through a 3.3 kΩ resistor. The required 4.5 mA. The start circuit will trigger with a 3 V drop in .1 µs with a duration greater than 1 µs.

CIRCUIT DESCRIPTION
OPTION 06, REMOTE CONTROL
SCHEMATIC #037226-7-1

With Option 06 installed, the Model 7110A may be operated remotely using single-line format. Control is provided over all RANGE and FUNCTION pushbuttons with DTL/TTL compatible ground true logic: "1" state (line called) = logic ground or +0.5 V dc maximum; "0" state (line not called) = open circuit or +2.2 V dc minimum. The connector type is a 24-contact Amphenol 57-40240 and mates with Amphenol 57-30240.

Press on the POWER and REMOTE pushbuttons, set the sample control to the desired rate, and remotely select the RANGE and FUNCTION of J208. The proper PIN and RANGE association is listed below:

OPTION 06, REMOTE PIN ASSIGNMENTS
(J208 REMOTE connector is Amphenol 57-40240)

Pin	Selected Function/Range[1]
1	REMOTE COMMON[2]
3	VDC
5	VAC
7	KΩ
9	RATIO
11	TEST
13	FILTER
15	AUTO
17	10,000
19	1000
20	100
21	10
22	1
23	.1

[1] The logic is ground true. If any line is low with respect to the Digital Common output line when not in REMOTE, the FUNCTION or RANGE called for by the front panel pushbuttons may be confused.

[2] This line is open when REMOTE is not called.

CIRCUIT DESCRIPTION
OPTION 08, REAR INPUT
FINAL ASSEMBLY #037181-4-1

Option 08 allows rear input on the HI, LO, and GUARD SIGNAL INPUT triaxial connectors; and the HI, LO, and COMMON Ω CURRENT SOURCE. See Page 3-9 for special cable and instructions for resistance measurement.

Installation Instructions:

1) Remove unit top and bottom covers (if installed).
2) Remove buttons from Ω CURRENT SOURCE SIGNAL INPUT holes in rear panel.
3) Release wire #'s 124, 126, 128, 131, 133 and 135 from tie "A".
4) Carefully remove shrink tubing from wire ends.
5) Install hardware, note position of insulating washers. Bend lug 203 as shown.
6) Re-tie cables as required.
7) Replace covers on unit.

INSTALLATION INSTRUCTIONS.

1. REMOVE UNIT TOP & BOTTOM COVERS (IF INSTALLED)
2. REMOVE BUTTONS FROM Ω & SIG HOLES IN REAR PANEL.
3. RELEASE WIRE #'S 124, 126, 128, 131, 133 & 135 FROM TIE 'A'
4. CAREFULLY REMOVE SHRINK TUBING FROM WIRE ENDS.
5. INSTALL HARDWARE, NOTE POSITION OF INSULATING WASHERS. BEND LUG 203 AS SHOWN
6. RE-TIE CABLES AS REQUIRED
7. REPLACE COVERS ON UNIT

CIRCUIT DESCRIPTION
OPTION 10, AC CONVERTER (rms)
FINAL ASSEMBLY #037734

The Option 10 AC Converter (rms) provides the Model 7110A Digital Multimeter with a true rms ac measurement capability. With this option, high-accuracy ac measurements of noise levels or distorted and complex waveforms may be made. This option consists of a single A9, AC Converter (rms) P.C. assembly board inserted in the A9 position on the A10 Analog Board and a new Guard/Calibration Cover installed. The averaging converter, A9, AC Converter, board, if in the unit, must be removed.

SPECIFICATIONS:

Ranges:	1, 10, 100, 1000 VAC.
Overrange:	30% except on 1000 VAC range.
Resolution:	0.001% range.
Overload:	750 V rms.
Superimposed dc:	1000 V dc (peak ac + dc may not exceed 1000 V.)
Maximum Crest Factor: (peak V/rms V)	7 at full scale and increasing down scale per: 7 X (V Range/V Input).
Input Impedance	1 MΩ shunted by 70 pF (120 pF with Option 08 Rear Input).
Accuracy:	Range 0.001 V to 1000 V:
	dc + 50 Hz to 10 kHz → ±0.1% Input ±0.05% Range,
	dc + 10 kHz to 20 kHz → ±0.3% Input ±0.2% Range,
	dc + 20 kHz to 100 kHz → ±1% Input ±0.5% Range,
	dc + 100 kHz to 300 kHz → ±3% Input ±0.5% Range,
	for 90 days from 18° C to 28° C.

Note: a) The customer must supply an input capacitor (approximately .1 μF, 1.2 kV) if the ac component only is to be measured.

b) The product of the input voltage and frequency ($E_{in} \cdot f$) should not exceed 2×10^7 V Hz.

Temperature Coefficients:	dc + 50 Hz to 10 kHz → (±0.015% Input ±0.004% Range)/°C from 0 to 18°C and 28 to 50°C.
Settling Time:	1 second to full scale, any range at specified accuracy.

CIRCUIT DESCRIPTION:

Option 10, A9, AC Converter changes an ac voltage to a dc voltage proportional to the rms value of the ac voltage. To accomplish the conversion, the A9, AC Converter P.C. board utilizes a switch selectable input attenuator, an input operational amplifier, and a true rms converter module.

When AC is selected, the HI input connector of the instrument is connected to the input of the AC Converter board on pin 15 & S. For the 10 V, 100 V, or 1000 V ranges, control signals turn on relays and close switches A9S1, A9S2, or A9S3 through a magnetic field generated by A9L1, A9L2, or A9L3. A9CR3, A9CR4, and A9CR5 are used to bleed the collapsing coil fields. All switches are open for the 1 V range. When one of these switches is closed, A9R9, in series with A9R1 as a ÷ 2 network, is shunted by a resistor-capacitor combination which increases the attenuation of the input by a factor of 10, 100, or 1000 for a total of 20, 200, or 2000 attenuation factor. No switches are needed for the X1 attenuation position or a factor-of-2 total attenuation. Overload protection is provided by diodes A9CR1 and A9CR2.

A9U1 is a gain-of-2 operational amplifier with a high-input impedance providing light loading on the input attenuator and a low output impedance for driving the following ac converter stage.

A9U2 is an rms ac-to-dc voltage converter module. The output dc voltage Vo at pin 5 & E for an input voltage Vi to the module A9U2 on pin 25 is given by the following relationship:

$$Vo = [1/p \int_o^p (Vi(t))^2 dt)]^{1/2}, \text{ where } p = \text{period}$$

t = pulse width time.

PIN ASSIGNMENT

OPTION 10, RMS TO DC CONVERTER MODULE ASSEMBLY #037730 REV 1

CIRCUIT DESCRIPTION
OPTION 301 or 302, A17, REMOTE PROGRAM
FINAL ASSEMBLY #037483-4-1

This option provides for the remote selection of all RANGE, FUNCTION, and FILTER operations. Depress the POWER and REMOTE pushbuttons on the front panel and select the desired SAMPLE RATE. Remote selection may then be made through input buffers, A17U1, and NAND gate, A17U3. Either negative true or positive true logic may be used. When using positive true logic, switch A17S1 must be placed in the positive position and solid wire jumpers placed in the input buffers.

Since all the input circuits operate in the same manner, only one circuit, $\overline{\text{VAC}}$, will be discussed. Depressing the REMOTE pushbutton completes the common ground circuit. The low into amplifier A17U3, pins 1, 2, 4 and 5, drives the output high, enabling NAND gates A17U4, A17U4, A17U5, and A17U6. The ground true $\overline{\text{VAC}}$ signal applied to pin 5, J208, drives the output of amplifier A17U1 high. This high, applied to A17U4 pin 10, with the high from amplifier A17U3 pin 6 applied to A17U4 pin 9, drives A17U4 pin 8 low. If positive true logic were being used, the input signal would be wired directly to input pin 10 of A17U4.

When operating the DMM from the local position, remote operation is inhibited by the interlocked switch arrangement. The remote common line is opened, the high applied to pins 1, 2, 4 and 5 of amplifier A17U3 drives the output low, inhibiting NAND gates A17U4, A17U5, and A17U6.

CIRCUIT DESCRIPTION
OPTION 303, REMOTE PROGRAMMING

Option 303 allows DTL/TTL compatible 8-4-2-1 parallel BCD control of remote programming lines to the Model 7110A and a program storage register. This option requires a 3-bit word for FUNCTION control and a separate 3-bit word for RANGE control. Remote control of front panel REMOTE selector is not provided.

An internal storage register allows BCD data to be "strobed" into the Model 7110A for storage and then commands removal. This is especially useful when programming is being controlled by a computer along with various instruments on a time-shared basis. The register holds data until cleared by an external "clear" pulse, resets automatically, and is readied to take new data.

Programming lines can be "called" at either the "1" or "0" state as specified by the customer. "Clear" pulse can either be at a "1" or "0" state as specified by the customer. Programming lines must be energized for at least 1 μs for storage feature. The "Clear" pulse must be at least 1 μs wide. Rise and fall times should not exceed 20% of total time width of pulses. Storage feature can be disabled, eliminating need for "clear" pulse when storage is not desired. This option must be accompanied by Option 06.

CIRCUIT DESCRIPTION
OPTION 304, INVERTED BCD

Option 304 provides inverted BCD data output per Option 05 but levels are inverted. This option must be accompanied by Option 05.

CIRCUIT DESCRIPTION
OPTION 305, BCD 4-2_2-2_1-1 OUTPUT, A13, A14
SCHEMATIC #037879

Option 305 presents a parallel BCD output code of 4-2_2-2_1-1 for all measurement data as well as flag lines for the PRINT command and BUSY conditions. All outputs are buffered, short-circuit proof, and fully isolated. The logic levels are TTL/DTL compatible, positive true.

"1" state (true) = +4 ±0.5 V dc, 6 kΩ source.
"0" state (false) = 0 ±0.5 V dc, 12 mA sink.

The external control inputs, $\overline{\text{INHIBIT RESET}}$, $\overline{\text{START}}$, and $\overline{\text{INHIBIT TRANS}}$ are ground true, however, and are activated by closure to SIGnal COMmon.

DECIMAL TO 4-2_2-2_1-1 BCD OUTPUT CONVERSION

CIRCUIT DESCRIPTION

The A14 BCD Connector, Option 305, is a buffer amplifier and signal conditioner which transmits data to a remote receiver. Signals from A11, Digital Count and Control, are routed through A14, BCD Connector, to A13 and J207. The BCD, decimal point, function, and control information is available to the remote equipment. Ground true BCD inputs from A11 are routed through inverters A14U1, U2, U3, U4, and U5, and converted to both positive and negative true signals. Decimal point information is applied through NAND gates, A14U5 & 6, and furnished to the receiver as the negative exponent of the measurement, $N \times 10^{a}$. Where (N) is the number measured and (a) is the negative exponent. A13U1-U5, U7-U10 converts the five digits of 8-4-2-1 BCD to the 4-2_2-2_1-1 OUTPUT.

Function signals are applied, at ground true level, to QUAD-INPUT NAND gates A1U11 and U6. The positive true BCD output is coded to designate the function. See BCD pin assignments, 305 Option. Polarity information is furnished through two inverters connected in tandem. If the signal at pin 2 of J2 is low, pin 4 of A14U1 is positive; and the polarity signal at pin 42, J207, is a positive-true indication of + polarity. A high input at pin 2 will result in a positive-true indication of - polarity at terminal 17 of J207. Overload is indicated in a like manner but uses only a single inverter. A low input results in a positive-true $\overline{\text{OL}}$ output through inverter A14U1. A high input is routed directly to pin 43 of J207, indicating an overload condition of, 1.3 times full scale.

Positive 5 V is furnished to the inverters and gates from J2, pin R, and 0 V from J2, pin F. A voltage divider network, A13C1, R3, R2, and R1, provide outputs of +0.5 V at pin 24 and +2.5 V at pin 25 of J207. This voltage is available as a reference voltage for comparison by properly equipped remote receivers. Control information signals to the DMM are ground true signals, routed directly through the board. $\overline{\text{INHIBIT RESET}}$, $\overline{\text{START}}$ and $\overline{\text{INHIBIT TRANSFER}}$ signals are received from the remote equipment. PRINT and BUSY are originated in the DMM. The open START signal is 5 V through a 3.3 kΩ resistor at a required 4.5 mA. The START circuit will trigger with a 3 V drop in .1 µs with a duration greater than 1 µs.

The following Tables, list the interconnections between the numbered pins and terminals on J207, A13, and A14.

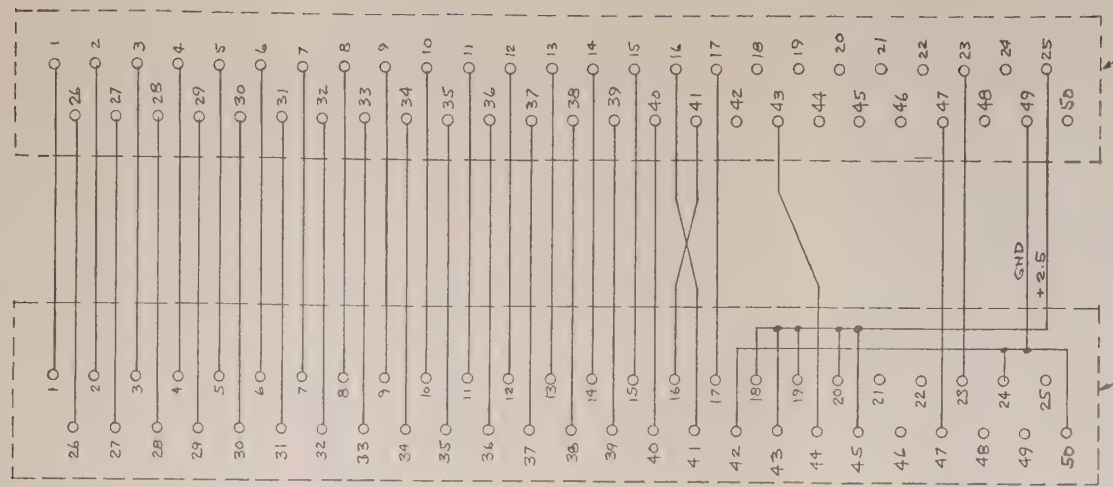
CABLE, MODEL 7110A TO HP 5050B ASSEMBLY #037528-4-1 REV B



DATA COLUMN	1	2	3	4	5	6	7	8	9	10
PRINT COLUMN	4	5	6	7	8	9	2	1	10	3

GND, TRUE INHIBIT
POS. TRUE PRINT

7- THIS CABLE COUPLES AN S.D. 7110 EQUIPPED WITH OPTION 05 TO AN HP 5050 B WITH +1248 CODE WHEEL INSTALLED.

1- DATA COLUMNS 1 THRU 6 ARE NUMERICAL DATA FROM MODEL 7110-05 WITH LEAST SIGNIFICANT DATA IN COLUMN 1

2- DATA COLUMN 7 HAS NEGATIVE EXPONENT (-N) OF 10. MULTIPLY THE DATA NUMBER ABOVE BY 10^{-N} TO PLACE DECIMAL POINT IN THE DATA NUMBER.

3- DATA COLUMN 8 HAS NUMBERS ASSIGNED TO SHOW THE FUNCTIONS AS FOLLOWS: mVDC - 1, VDC - 2, VAC - 8, KΩ - 9, MΩ - 4, RATIO - 6, RATIO x 10^{-3} - 7, TEST OR NO FUNCTION - 0, BAD RANGE - *.

4- DATA COLUMN 9 HAS + AND - SIGN DATA TO SHOW POLARITY.

5- DATA COLUMN 10 HAS - TO PRECEDE EXPONENT IN NOTE 2 OR * TO SHOW WHEN NUMERICAL DATA IS OFF SCALE, ≥130000.

6- PRINT OUT FREQUENCY IS DETERMINED BY THE SETTING OF THE FRONT PANEL SAMPLE RATE CONTROL OF THE 7110. MAXIMUM RATE DETERMINED BY PRINTER.

CHAPTER 7
SUPPLEMENTAL INFORMATION

7.1 INTRODUCTION

This chapter contains revised or updated information reflecting changes in production requirements of this instrument. This information can include changes in assembly/schematic drawings, parts lists, operating instructions, calibration procedures, etc. Changes to parts lists will contain only the added parts, plus a list of deleted items. The supplemental pages for each assembly will be identified with the words SUPPLEMENTAL INFORMATION, followed by the nomenclature of the board. For example, if the A3, Input Amplifier P.C. Board is to be changed, the package identification will read as follows:

MODEL 7110A
SUPPLEMENTAL INFORMATION
A3, INPUT AMPLIFIER P.C. BOARD
SCHEMATIC #37176

Page identification for an October 19XX change will be:

37176-10-XX SUPPLEMENT; page numbering will be in numerical order using the same page numbers as the basic information with the addition of an "A". The A3, Input Amplifier P.C. Board supplemental pages will be A3-1A, A3-2A etc.
